BLOOD LOSS IN SURGICAL OPERATIONS

CHAIRMAN'S ADDRESS

FREDERICK A. COLLER, M.D.

CLARENCE E. CROOK, M.D.

AND

VIVIAN IOB, Ph.D.

ANN ARBOR, MICH.

The amount of blood lost during surgical operations of various types has been measured and reported by a number of observers. The facts disclosed by these observations have not been generally recognized, nor has their practical importance been sufficiently emphasized. In order to bring attention to this technical problem, the literature on it has been reviewed and further studies have been made as are here reported. Shock appearing during and after operation is still the apprehension of the surgeon and a menace to the patient. During the past three years an enormous amount of investigation on the subject of shock has added materially to our knowledge of it. One fact, however, remains clear: There is no single reliable test or clinical sign of impending shock, especially in anesthetic and postanesthetic states. By the time shock is recognized as such it is well established. Our ability to treat shock has improved, but it is far from satisfactory. The earlier the treatment is instituted the better the results, and if its advent is anticipated it may be prevented far easier than it may be cured. Though there are no positive early tests of impending shock, there is a large background of clinical observation from which to deduce that shock will appear under certain circumstances—burns involving 20 per cent or more of the body surface, severe dehydration, multiple fractures and wounds, crushing injuries, exposure to cold air or immersion in cold water, and extensive blood loss. It is well known that shock develops more readily with a given injury if there exists malnutrition or starvation, anemia, dehydration, physical or mental exhaustion, chronic illness or prolonged bed rest. With these facts available, one should be able to anticipate and usually prevent shock in the surgery in civilian hospitals.

In 1924 Gatch and Little¹ reported the first study of blood loss during some of the more common operations in general surgery in which accurate measurements of the losses were made. They pointed out that the amount of blood lost in the ordinary laparotomy is

not great but that in operations involving extensive dissection the loss may be excessive. They concluded that a patient in fairly good physical condition could lose from 600 to 700 cc. of blood without any apparent harmful effect on the postoperative course. Likewise an adult in good health does not manifest any serious effect from hemorrhage until the amount of blood lost is between 800 and 1,000 cc. Alexander Blain² in 1929, in commenting on his experience with 3,000 transfusions, stated that the amount of blood lost at operation is often several times greater than that estimated by the surgeon. He urged the preoperative correction of anemia and the immediate replacement of blood lost during operation and condemned delay in giving blood transfusions until after shock had developed. Coller and Maddock³ in 1932 measured blood loss during some of the ordinary operations and concluded that the amount of blood lost is always greater than the surgeon estimates. Windfeld⁴ in 1937 made direct measurements of blood loss during operations and concluded that the loss is often far greater than supposed, so that without appearing dangerous it may reduce the volume of the circulating blood considerably. Determination of hemoglobin concentrations before and after operation did not give quantitative information regarding the amount of blood lost. Pilcher and Sheard⁵ in 1937 estimated the blood loss by a photometric method and found that the average loss from prostatic resections was 479 cc. This finding stimulated efforts to secure better hemostasis, and in a second series studied following alterations in technic the average loss was reduced to 291 cc. A group of 49 general surgical cases was studied for comparison. Hubly⁶ in 1937 used this method to determine the hemostatic effect of congo red. White, Whitlaw, Sweet and Hurwitt⁷ in 1938 made an exhaustive study of blood loss in neurosurgical operations. They found that in the course of extensive intracranial operations the average loss was from 500 to 1,500 cc. They concluded that these patients rarely develop the typical shock state unless the loss is over 1,200 cc. or unless the loss is rapid. They urged greater attention to hemostasis at the expense of time and advocated discontinuing the operation if the loss exceeded 1,200 to 1,500 cc. Stewart and Rourke⁸ in 1938 studied changes in blood and

interstitial fluid resulting from surgical operation and ether anesthesia. They pointed out that the hematocrit changes induced by trauma and blood loss of operation are not proportional to the blood loss and that the structurally important elements of blood plasma, that is protein, sodium and chloride, are accurately sustained by the body. They emphasized the fallacy of assuming a quantitative relationship between the changes in the concentration of hemoglobin or plasma protein and changes in the plasma volume.

Nadal⁹ in 1939 studied blood loss in orthopedic operations and found that patients losing over 20 per cent of the blood volume frequently showed clinical signs of shock. Leriche and Vasilaros¹⁰ in 1939

TABLE 1.—Blood Loss in Operations of Various Kinds in 626 Cases Compiled from the Literature

Operations	Number of Cases	Blood Loss

TABLE 2.—Relationship of Blood Loss to Total Blood Volume

Weight	Total Blood Volume	100 Cc. Loss
10 lbs.	450 cc.	22.0 %
20 lbs.	890 cc.	11.0 %
40 lbs.	1,600 cc.	6.2 %
80 lbs.	2,825 cc.	3.6 %
140 lbs.	5,000 cc.	2.0 %
200 lbs.	7,000 cc.	1.4 %

reported measurements of blood loss in twenty-nine operations of diverse character. They concluded that a loss even as small as 500 cc. of blood is not a matter of indifference to a body which is called on to effect the repair of trauma and disease. Nesbit and Conger¹¹ in 1941 measured blood loss associated with transurethral prostatectomy and stated that this determination is easily carried out at the time of operation and should be made a routine procedure, so that untoward blood losses may be immediately appreciated and corrected by transfusion. They urge the use of whole blood to replace the blood loss accurately. Wangensteen¹² in 1942 described a gravimetric method for

determining the status of hydration and blood loss during operation. He advocated the replacement of minor blood loss by an amount of plasma 100 to 200 cc. greater than the blood lost, or if the loss is excessive it should be replaced by whole blood. He found the average blood loss from gastric resection to be 300 to 500 cc. In 1942 Buxton and White¹³ measured blood loss in 109 patients undergoing operations on and in the thorax. The loss in these operations was exceptionally large, averaging about 700 cc. for each stage thoracoplasty, 1,600 cc. in lobectomy and about the same for pneumonectomy. Large transfusions during operation were advised. Oppenheim, Pack, Abels and Rhoads¹⁴ in 1944 measured the amounts of blood lost in various abdominal operations and described a simplified method for carrying out this technique. The amount of blood lost was not excessive. However, they felt that a transfusion of 500 to 600 cc. of blood during the operation is of great benefit to patients operated on for cancer of the gastrointestinal tract. They advised the routine determination of blood loss especially in elderly patients with cardiovascular insufficiency in order to prevent the administration of unnecessarily large amounts of fluid.

In table 1 are shown blood losses from 626 operations collected from the data of these authors. The cases are grouped according to the types of operation, and the maximal, minimal and average losses are given. It was the unanimous conclusion of all who studied this problem that the blood losses in nearly every operation were greater than expected by the surgeon. The constant ooze of blood from large vascular fields leads to a large loss, of which the surgeon is frequently not cognizant. Accurate measurement of blood loss leads to an appreciation of the importance of better hemostasis. Nevertheless at times, in spite of every effort at hemostasis, the loss will still be large and transfusions should be planned in advance.

Analysis of the literature impresses one with the fact that not enough emphasis has been placed on the relation of the amount of blood lost to the total blood volume. Since the blood volume varies with the weight of the patient, it makes a vital difference whether a given amount of blood is lost from a large adult or from a small child. In table 2 are shown some figures illustrating the relationship of a 100 cc. blood loss to the blood volume in patients of differing weights.¹⁵ Blood comprises 77.7 cc. per kilogram of body weight in the male and 66.1 cc. per kilogram in the female.¹⁶ For all practical purposes one thirteenth of the body weight is blood, and cells make up 45 per cent of the blood volume in men and 40 per cent in women. A simple method of calculating blood volume is to allow 30 cc. of blood for every pound or 75 cc. for each kilogram of body weight. Stewart and Rourke⁸ showed blood loss in terms of percentage of total blood volume but did not comment on its critical relation to weight. Nadal⁹ pointed out the important relationship between the size of the patient and the amount of blood that could be lost before signs of shock would appear.

Since several of the preceding studies were carried out in the University Hospital¹⁷ our surgical staff has come to realize the importance of a knowledge of blood loss during operation. Further investigations have been made to stress the necessity of admitting that blood will be lost, that its approximate amount should be known and that it should be replaced by blood. Fifty cases were studied, and 42 have been selected for presentation. The method used for determining blood loss was essentially that of Gatch and Little with the following exceptions:

1. Oxyhemoglobin was measured in the Evelyn photoelectric colorimeter.

2. The fluid from aspirator bottle, instrument and glove washings was kept separate from the washtub fluid.

3. The sample from the 50 liters of washtub fluid was taken directly from the washtub before the drapes and gauze sponges were removed. Controlled washings, using known amounts of blood on sample outfits of drapes and sponges, yielded an average recovery of 95 per cent. The detailed method was as follows:

With Evelyn's method, oxyhemoglobin was determined on the solution containing equal volumes of the following fractions:

1. Fluid from drapes and sponges extracted in washing machine in 50 liters of distilled water for two hours.

2. Aspirated fluid and water used to wash instruments and gloves diluted to 5 liters, or to 10 liters if necessary, and finally diluted 1:10, or 1:5, with distilled water. The solution was centrifuged to clarify it and diluted 1:1 with distilled water.

The patient's preoperative concentration of hemoglobin was determined at the same time.

Calculations:

$$\text{Gm. Hb lost} = \text{Gm. \% Hb from blood curve} \times \frac{1,000}{250}$$
$$\frac{\text{Hb lost}}{\text{pt's. preop. Hb}} \times 100 = \text{cc. blood lost}$$

The cases here presented were selected for study on the basis that, owing to their character, a high blood loss might be expected; and they were limited chiefly to five categories to facilitate comparison. Particular interest was centered in changes in the blood picture associated with hemorrhage. Therefore many patients, whose blood loss was minimal were excluded from the presentation. Consequently the blood loss in these groups does not represent average results from routine operations of their types. The operations were performed by ten surgeons from the resident staff.

In tables 3 to 8 are shown measured blood loss and its percentage of total blood volume, intravenous solutions given in the operating room, blood transfusions given during or immediately after operation, and the degree of hypotension stated in terms of 1 to 4 plus, in patients during various types of operation. In table 3 the blood loss from radical mastectomy is slightly higher than found by others, but, since these operations are always accompanied by such losses, transfusion during these operations has been made a routine at the University Hospital by our staff. Patient 27 developed a moderate hypotension, which was corrected by transfusion of blood equal in amount to the loss. In table 4 the blood loss associated with thyroidectomy is shown. These patients all presented large, recurrent or unusually toxic goiters, and the average blood loss was much higher than found in routine thyroidectomies. In 2 instances the loss was above 25 per cent of the blood volume, but the surgeon realized this fact and replaced the lost blood by transfusion during the operation.

In table 5 is shown a group of patients presenting difficult technical problems in surgery of the biliary tract. Many had been operated on previously. The majority were jaundiced, and in all the common duct was explored or reconstructed. The operations were long and the blood loss averaged nearly 600 cc. Case 41 is of interest since the blood loss of 1,065 cc. represented 41 per cent of the blood volume; the patient was emaciated and weighed only 86 pounds (39 Kg.). This

patient developed an alarming shock state from the operative trauma, blood loss and bile peritonitis and was given 3,000 cc. of blood in the next forty-eight hours, after which convalescence was relatively uneventful. Contrast this 41 per cent loss with that of case 21, in which a much larger amount of blood, 1,455 cc., was lost, the latter amount representing only 27 per cent of the total blood volume. Both cases required extensive replacement by blood. In operations of this character performed on undernourished and jaundiced patients, one should always plan on adequate replacement of the blood loss. The routine immediate replacement of blood in these patients was found to be inadequate at the

time of this study, and we have since planned for a liter of blood to be given during operation.

accompanied by a blood loss averaging 600 cc. In table 8 is shown the relatively large blood losses resulting from operation in which large body surfaces are opened. This blood loss is from multiple small rather

than from single large vessels. The use of gauze packs as hemostatic agents tends to obscure hemorrhage rather than control it. Table 3 is a similar example of operations on large body surfaces.

Concurrently with the blood loss determinations, observations were made of changes in hematocrit and hemoglobin and plasma protein concentration before and after operation. These findings are listed in relation to blood loss in table 9, and deductions from them agree with those of Stewart and Rourke.¹⁸ There was found no correlation between the amount of blood lost and the simultaneous changes in hematocrit, hemoglobin and concentration of plasma protein immediately before and

after operation. These determinations, therefore, cannot be used to estimate the need for blood volume replacement during and after operation. Obviously, it follows that if one wishes to know the amount of blood lost in any operation one must depend on direct measurement. This approach is not often practical, in which event one must rely primarily on a knowledge of average losses to provide a basis for the replacement of blood loss during operation. Additional blood may be given if the clinical state of the individual demands it. We believe that even minimal blood loss retards convalescence; that all loss over 300 cc. in healthy adults should be replaced and that all blood loss in operations on aged, undernourished, seriously ill or bedfast patients should be replaced with equal quantities of blood.

18 In table 9 the data were determined by use of the colorimeter described by K. A. J. Biol. Chem. 115:63, 1936; plasma protein determined by use of the method of Pregl, I.: Die Quantitative organische Chemie, 1923.

CONCLUSIONS

From this study we have drawn the following conclusions:

1. No correlation exists among the amount of blood lost and changes in hematocrit, hemoglobin and plasma protein concentrations before and after operation.
2. A knowledge of blood loss during operation as available in the literature offers a practical basis for planned transfusions during operation.
3. The patient is benefited most when the blood loss is replaced by blood, given as the loss occurs.

THE CLINICAL MANIFESTATIONS OF
LEPTOSPIROSIS IN LOUISIANA

HARRY A. SENEKJIE, M.D.
NEW ORLEANS

The classic description of infectious jaundice was presented by Weil¹ in 1886, who reported 4 cases in which there was a sudden onset of fever, chills, prostration, jaundice, hepatosplenomegaly, hemorrhagic tendency and renal failure. All 4 patients recovered. Inada and his associates² discovered the causative agent, and Noguchi³ named it *Leptospira icterohemorrhagiae*. Stimson⁴ described a spirochete in the organs of a patient in New Orleans who died presumably of yellow fever and called it *Spirochaeta interrogans*. Wadsworth⁵ introduced laboratory methods for the diagnosis of Weil's disease in the United States. Jeghers,⁶ Packhamian,⁷ Larson⁸ and others have reported numerous cases from this country.

Spirochetal jaundice is not a proper term, because jaundice is present only in about two thirds of the cases. Weil's disease refers to infection with *Leptospira icterohemorrhagiae*. *Leptospira canicola* infections occur in man and dog. In this country canine leptospirosis was reported by Meyer and his associates⁹ in California, by Molner and Kasper¹⁰ in Michigan, by Clara Raven¹¹ in Pennsylvania and by Bruno, Wilen and Snively¹² in Louisiana; but Tiffany and Mar-

torana¹³ did not find any evidence of this infection in New York. The European *L. canicola* infections do not give rise to jaundice in human beings or dogs, but the American type may be icterogenic.

Vervoot, cited by Strong,¹⁴ found in cases of pseudo-dengue in Java a leptospira which he called *Leptospira pyrogenes*. This disease is endemic in plantations and may be associated with jaundice and rash. In southeastern Europe Tarassoff¹⁵ and Korthof¹⁶ reported a mild type of leptospirosis in which there was no jaundice. *Leptospira grippotyphosa* is the name given to the causative organism.

Leptospira hebdomadis is the causative organism of seven day fever, and *Leptospira autumnalis* is the causative agent of autumn fever in Japan.

Since leptospirosis is a general term which includes all the leptospiral infections, it is advisable to use specific terms, such as leptospirosis icterohemorrhagiae and leptospirosis canicola or canicola fever.

EPIDEMIOLOGY

Rat to rat transmission is accomplished through the contamination of the food by the excreta of the infected rats and less commonly through sexual intercourse among the rats. The incidence of infection is higher among the older than among the younger rats.

Rat to man transmission occurs mainly through the contamination of human food with the excreta of infected rats. Rarely a rat bite may be responsible for infection. The handling of rats is a frequent method of infection, so that the disease is found among sewer workers, harvesters, farmers, sugar cane cutters, fishermen, fish handlers, slaughterhouse employees and miners. Occasionally the infection is acquired by bathing in water contaminated with pathogenic leptospires. Dog to dog and dog to man transmission in canicola infection is similar to that of the rat borne leptospirosis.

In this series of 30 patients, the groups represented were cooks, gardeners, laborers, farmers, carpenters, porters, warehouse employees, truck drivers and orphans. In most of these cases there was a definite history of contact with rats and dogs.

INCIDENCE

The total hospital admissions to the Louisiana State Charity Hospital of New Orleans from September 1939 to February 1944 were 236,466, while the patients admitted to general medicine during this period were 37,610. During this period there were 28 cases of leptospirosis diagnosed by laboratory methods. Thus the ratio is 1 case of leptospirosis to every 8,445 general admissions and 1 case to every 1,343 general medicine inpatients.

Seven of the 30 patients were Negroes, and the only female in this series was a Negro woman. The age incidence varied from 14 to 68 years, but the majority of the patients were 20 to 40 years old.

The patients were admitted to the hospital from the second to the ninth day after the onset of the disease, but the majority were admitted on the fourth to the sixth day of the disease. The period of hospitalization

From the Department of Tropical Medicine, Tulane University of Louisiana.

Permission to study their cases, which are included in this report, was granted by Dr. John H. Musser, professor of medicine at Tulane University School of Medicine and senior visiting physician at the Charity Hospital in New Orleans; by Dr. Edgar Hull, professor of medicine at Louisiana State University School of Medicine and senior visiting physician at the Charity Hospital in New Orleans; by Dr. O. P. Daly, director of the Charity Hospital in New Orleans, and by Dr. F. C. Coleman of Touro Infirmary in New Orleans. Dr. Musser and Dr. E. C. Faust gave many valuable suggestions in the preparation of this paper.

ranged from three to thirty-eight days. Four patients were hospitalized for three to nine days, 5 for ten to nineteen days, 8 for twenty to twenty-nine days and 11 for thirty to thirty-nine days. The duration of the fever ranged from eight to thirty-seven days. In 10 instances the duration of the fever was one to two weeks, in 5 two to three weeks, in 10 three to four weeks and in 4 four to five weeks. Three of the patients died in the second week and 2 in the fourth week of the disease.

CLINICAL FEATURES

Leptospirosis is a hepatorenal syndrome. In the anicteric cases the involvement of the liver is very slight, but there is always a mild hepatitis. In the majority of the cases there is a moderately severe hepatitis, and in some it is very severe. Similarly the kidney lesion may be very mild, moderate or very severe.

Icterus is due to partial biliary obstruction caused by inflammation of the biliary ducts. There is injury and damage of the hepatic cells, and this is a reversible phenomenon. Hemolysis does not play an important role in the causation of the jaundice. The renal lesion is of toxic origin and is primarily tubular. Hemorrhagic phenomena are a characteristic part of the clinical picture. They are apparently the result of the

according to Strasburger and Thill¹⁷ from the third to the ninth day, according to Martin and Pettit¹⁸ on the fifth day, and according to Ashe and his associates¹⁹ from the third to the ninth day. The onset of jaundice was very gradual. Clinically the first evidence was a subicteric hue of the scleras, which progressively became icteric. Two of our patients (6½ per cent) were anicteric. Strong¹⁴ has stated that in Japan 60 per cent of the patients were icteric, while in Europe 13 to 58 per cent were anicteric. Larson⁸ reported 7 anicteric patients and inapparent icterus in 51 in the United States and Puerto Rico. The duration of this stage was seven to ten days in the series herein analyzed.

The liver was enlarged, tender and often painful. Usually it was about 2 fingerbreadths palpable, but rarely it reached the umbilicus. In 3 cases (10 per cent) the liver was not enlarged yet there was definite jaundice. In the 2 anicteric cases the liver was palpable. Hepatitis appeared to be present in both the icteric and the anicteric cases.

Splenomegaly was present in 3 cases (10 per cent). The spleen was soft and palpable 1 to 4 cm. below the costal margin. Clinically it resembled the splenomegaly of typhoid.

During this stage the gastrointestinal symptoms had a tendency to subside. Vomiting, arthralgia, myalgia and headache were not distressing, but the patient was toxic, apathetic and prostrated and had a continued fever. There was moderate abdominal distention due to low grade ileus and diminished peristalsis.

Hemorrhagic phenomena were present in 16 cases (53.3 per cent). Conjunctival injection, hemorrhages into the eye, petechial hemorrhages, ecchymotic spots in the skin and mucous membranes, epistaxis, melena, hematemesis, hemoptysis and bleeding from the gums were observed, but no demonstrable rashes were noticed.

With the appearance of icterus the pulse had a tendency to become slow. Pruritus occurred in 16½ per cent of the patients, but herpes labialis was not observed. There was no generalized lymphadenopathy, but 4 patients (13.3 per cent) had palpable enlarged lymph nodes in the anterior cervical and inguinal regions, which were painless and subsided after recovery.

Respiratory Symptoms.—These were present in 12 instances (40 per cent). The following were observed: cough, expectoration, rarely blood tinged sputum, pharyngitis, bronchitis and at times patchy consolidation of the lungs. Not infrequently the clinical diagnosis of atypical or virus pneumonia was made in anicteric cases with the finding of blood tinged sputum. With the appearance of jaundice and later on the basis of the urinary findings, the presumptive diagnosis of leptospirosis was made.

Cardiovascular System.—The blood pressure was low. At times the heart was enlarged and hemic murmurs were detected. Gallop rhythm, tachycardia developing into bradycardia, premature beats, auricular fibrillation and flutter, pericardial friction rub and evidence of myocardial disease were also observed. The electrocardiogram revealed prolongation of the QT interval and PR interval, defective auriculoventricular

TABLE 1.—Ratio of Leptospirosis Among Hospital Admissions

Year	General Admissions	General Medicine Admissions
1941.....	1 to 8,581	1 to 1,436
1942.....	1 to 4,000	1 to 725
1943.....	1 to 5,263	1 to 760
1939-1944.....	1 to 8,445	1 to 1,342

local toxic action of the leptospirae on the capillary endothelium and a deficiency of vitamin K due to liver dysfunction.

Septicemic Stage.—The incubation period of the disease varied from one to two weeks. The onset of the disease in 20 of the cases was sudden, with either a chilly sensation or a distinct chill, followed by fever, nausea, vomiting, arthralgia, myalgia, frontal headache, prostration, anorexia, diarrhea or constipation. Epigastric pain and discomfort, pain and tenderness in the muscles of the legs and back, as well as painful ocular movements, were very common. Infection of the upper part of the respiratory tract with cough and bloody sputum might simulate atypical pneumonia. The temperature of the patient varied between 101 and 104 F. The respiration was normal or rapid, the pulse was accelerated and there was a tendency to hypotension. Conjunctival injection was present in half of the cases. There was at times a mild injection, but in some cases severe hemorrhages took place. There were usually no hepatic or urinary disturbances, despite the fact that the fever continued to be high. Leptospirae occurred in the peripheral blood and were demonstrated on dark field examination, but there were no circulating antibodies. The duration of these symptoms was about three to seven days.

Hepatic, or Icteric, Stage.—The majority of the patients became icteric about the sixth to the seventh day after the onset of the disease. In a few cases jaundice developed as early as the second or third day and in some as late as the ninth day. According to Inada² jaundice appears in the middle of the first week.

conduction, functional or actual incomplete auriculo-ventricular block, low T waves, blocked-auricular-beats, sinus tachycardia, low voltage, with wide and slurred QRS complex. During convalescence the heart and the electrocardiographic findings gradually returned to normal.

Central Nervous System.—Headache, delirium, apathy, hallucinations, disorientation and restlessness were among the common observations. In severely ill patients there were rigidity of the neck and retraction of the head, loss of consciousness and symptoms of meningeal irritation. The following case is interesting from the point of view of the findings:

R. R., a white man aged 52, was admitted to the Charity Hospital on Aug. 7, 1943 with the complaint of headache, chills and fever since July 31 and the development of jaundice on August 5. He worked in a butcher's shop where there were many rats. On admission the temperature was 101 F., the pulse rate 115 and the respiratory rate 40. On August 8 he became irrational and incontinent, and gallop rhythm with a 200 per minute ventricular rate developed. On August 10 the neck became stiff and the patient was completely irrational. Leptospiras were observed in the blood and cerebrospinal fluid on the dark field examination. The pressure of the cerebrospinal fluid was 74, the color icteric, the cell count normal, the Pandy reaction 4 plus, proteins 57 mg. and chlorides 625 mg. per hundred cubic centimeters. All the agglutination reactions as well as the blood cultures were negative. The blood picture showed 4.95 million erythrocytes with 15.8 Gm. of hemoglobin, 27,800 white blood cells with 93 per cent polymorphonuclears. The urine had albumin (1 plus), no sugar and a specific gravity of 1.010, with numerous white and red blood cells and granular casts. The blood urea nitrogen level was 27.6 mg., icterus index 199.8, van den Bergh 40 units direct and the clotting time five minutes. The patient was given digitalis, infusions of dextrose, transfusions and other treatment but died on August 10, with a temperature of 107 F.

Leptospiras were demonstrated in the blood and urine by the dark field method. Agglutinins appeared in the blood but did not rise to diagnostic titer during the hepatic stage.

Nephritic, or Uremic, Stage.—The transition from the hepatic to the nephritic stage was gradual and not clearcut. Even during the septicemic stage there was some diminution in the urinary output, mild albuminuria and occasional red and white blood cells. During the hepatic stage there was oliguria, with red and white blood cells and occasional casts in the urine, but there was no retention of metabolites in the blood. Now symptoms of kidney failure became superimposed on those of hepatic failure, so that a state of cholemia and uremia resulted. The clinical diagnosis of Weil's disease was confirmed in a patient who had a sudden onset of fever with chills, arthralgia, myalgia, icterus and in whom kidney failure finally developed.

All patients had oliguria, while 5 (16½ per cent) had anuria. Albuminuria from 1 plus to 4 plus was present in 80 per cent of the cases, while glycosuria was present in 10 per cent. Red and white blood cells and hyaline or granular casts were present in 80 per cent of the cases. There was a steady rise in the blood pressure, a retention of nitrogenous metabolites, lowering of the kidney function tests (such as excretion of phenolsulfonphthalein) and fixation of the specific gravity of the urine but no hyperglycemia. The patient became irrational, restless and drowsy, with a continuous tendency to somnolence. There was disorientation as to time, place and person, and loss of sphincter control, so that the urinary output could not be measured. He became extremely toxic and semicomatose and finally died of uremia and hyperpyrexia. Lepto-

spiras could not be demonstrated in the blood, but they were found in the urine. The agglutinins rose to a diagnostic titer of 1:300 or above.

Convalescence.—In favorable cases the intensity of the jaundice and uremia gradually diminished, and there began to be secretion of more urine. The temperature began to fall by lysis, the hemorrhagic phenomena subsided and the patient became free from symptoms but suffered from general weakness for a few weeks. Ordinarily convalescence occurred in the third week, but it might be as late as the fifth or sixth week. The last symptom to disappear was jaundice, which at times persisted a few weeks after the temperature had become normal. In about 25 per cent of the cases in the third to the fifth week of the disease there was a relapse, which suddenly occurred with all the accompanying symptoms of the disease but was usually milder and lasted only two to seven days. Leptospiras were found in the urine, but the titer of the agglutinins in the blood was high.

LABORATORY DATA

Hematologic Observations.—The blood picture was one of microcytic hypochromic anemia. The blood count varied from normal to 1.81 million per cubic millimeter, with an average of about 3.5 million. There was occasionally a slight reduction in the platelet count. The bleeding and coagulation times were not altered. The prothrombin time was determined in 7 cases, and 6 showed moderate to considerable prolongation. The lowest was 40 per cent. The fragility of the erythrocytes was not altered. The sedimentation rate was increased. There was an active leukocytosis in 83 per cent of the cases, ranging from 10,000 to 30,000. In 6 instances the white cell count was within normal limits. There was a striking increase in the number of neutrophils with a shift to the left.

Blood Chemistry.—The van den Bergh reaction was direct. In the beginning of the disease the reaction was not intense, but progressively the icterus index and blood bilirubin levels reached as high as 300 units and 90 mg. per hundred cubic centimeters respectively. The blood chlorides, sugar and cholesterol were not altered. The blood urea and uric acid began to rise, and they reached their peak during the nephritic stage. Usually the urea nitrogen in the blood was around 50 mg., but the highest level in this series was 177 mg. per hundred cubic centimeters. The blood creatinine was determined at frequent intervals. Late during the course of the disease it rose to very high levels. Ten mg. per hundred cubic centimeters of creatinine was found to be a bad prognostic sign, and when the level reached 12 to 14 mg. the outcome of the infection was invariably fatal. The highest level in the present series was 17.8 mg. There was some evidence of reduction in the serum proteins. The carbon dioxide combining power of the plasma was normal or reduced. The hippuric acid test for liver function was reduced, and the cephalin cholesterol flocculation test was at times positive.

Urinary Observations.—The urinary output was diminished, and in the fatal cases there was anuria. Albumin, red and white blood cells, hyaline and granular casts, bile pigments and excess of urobilinogen were present. Glycosuria occurred in 10 per cent of the cases. The phenolsulfonphthalein excretion was reduced.

Stools.—Four patients (13.3 per cent) had clay colored stools.

COMPLICATIONS

Severe hemorrhages may be the usual features of the disease. Pneumonia, meningismus and meningitis are unusual. Multiple bacterial abscesses of the liver, myocarditis, iridocyclitis and optic neuritis have also been reported.

MORTALITY

Strong¹⁴ stated that in Japan the mortality rate is 48 per cent while in Europe it is 4 to 32 per cent. In this series the mortality rate was 16⅔ per cent. A white man aged 39 died on the eighth day of the disease; a Negro man aged 68 died on the twenty-seventh day of the disease; a white man aged 49 died on the thirteenth day; a white man aged 53 died on the eleventh day, and a white man aged 43 died on the twenty-fifth day of the disease. Patients may die at any stage of the disease, but young patients invariably recovered.

LABORATORY DIAGNOSIS

In 1939 laboratory methods for the diagnosis of Weil's disease were introduced in New Orleans. Since that time 45 patients have been admitted to the Charity Hospital with the probable diagnosis of Weil's disease, and 30 were found to have leptospirosis by diagnostic laboratory methods; hence 66⅔ per cent of the presumptive diagnoses were confirmed. In 1 case the diagnosis was Weil's disease on admission. In 5 other cases the admission diagnosis was catarrhal jaundice.

TABLE 2.—Summary of the Agglutinin Titers

Cases	Titer
10.....	1:300 to 1:1,000
3.....	1:3,000
3.....	1:10,000
1.....	1:30,000
2.....	1:100,000
5.....	1:1,000,000

Multiple clinical diagnoses were given in every case, including pneumonia and atypical pneumonia, cholecystitis, hepatitis, typhus, typhoid, subacute bacterial endocarditis, abscess of the liver, yellow fever, acute yellow atrophy of the liver, nephritis, tularemia, meningitis, malaria, brucellosis, peripheral neuritis and avitaminosis.

The protean nature of the manifestations of leptospiral infections is well recognized. Therefore all clinical diagnoses must be proved by laboratory methods. During the septicemic and hepatic stages the blood is teeming with leptospires, and the dark field examination of the blood by an experienced investigator is the best diagnostic method. Schultz²⁰ observed pseudospirochetes arising from red blood cells, which can be easily mistaken for leptospires by an inexperienced worker. In this series 7 cases (23.3 per cent) were diagnosed by the finding of leptospires in the dark field. In 1 case the organisms were found as late as the tenth day after the onset of the disease. If the blood of the patients had been examined routinely during the early stages, the percentage would undoubtedly have been higher. In 1 case leptospires were found in the urine and in the cerebrospinal fluid in another case.

In 24 cases (80 per cent) the diagnosis was made by the agglutination reaction. The titer began to rise during the hepatic stage, reached the diagnostic level during the nephritic stage and was at its peak during

convalescence. In my opinion the diagnostic titer must be at least 1:300, with a steady rise in the titer. Anamnestic reaction may be observed in persons who have residual agglutinins in the blood due to a previous clinical or subclinical infection and in whom a fever develops which is not related to leptospirosis. In such cases there may be an early rise in the agglutinin titer, with fall later on.

Agglutinin titers in a case of leptospirosis.

The following case report illustrates the way in which the agglutinin titer may remain at a low level during the course of the disease and then rise very rapidly toward the end, as shown in the accompanying chart.

J. Y., a white man aged 56, was admitted to the hospital on Jan. 12, 1942, the seventh day of his illness, with a tentative admission diagnosis of Weil's disease, catarrhal jaundice, yellow fever or acute yellow atrophy of the liver, because he was having chills, fever, nausea, vomiting, articular and muscular pains, headache, epigastric pain, jaundice, conjunctival injection, auricular premature beats, palpable anterior cervical lymph nodes, leukocytosis of 30,000 with 92 per cent neutrophils and 3.25 million erythrocytes, direct van den Bergh reaction and icterus index of 120 units, with urobilinogen and bilirubin in the urine. The blood pressure was 140/70; the blood urea nitrogen level was 37 mg. per hundred cubic centimeters; 0.22 Gm. of sodium benzoate was detoxified, and 50 per cent of injected bromsulphalein was excreted in five minutes, 0 in fifteen and 0 in thirty minutes. The duration of the disease was thirty-five days. The patient was hospitalized thirty-seven days.

Leptospira canicola infection was reported by Bruno and his associates.¹² The serum of these patients agglutinated *L. canicola* in 1:10,000 and 1:1,000,000

TABLE 3.—Important Data in Fatal Cases of Leptospirosis

dilutions respectively and *L. icterohemorrhagiae* in 1:1,000 and 1:1,000,000 respectively. There is no laboratory evidence that dogs in New Orleans suffer from canicola fever, even though jaundice is at times present in local dogs. Cultural methods and guinea pig inoculations were performed in some of the present cases, but the results have been consistently negative, even though young guinea pigs and large inoculums were used. Lately Lederle's slide agglutination antigen has been employed for the quick diagnosis of the disease, but it requires checking with the regular agglutination technic.

20. Schultz, E. W.: The Pseudospirochetes Derived from the Red Blood Cells, *J. Lab. & Clin. Med.* 8:375, 1923.

Leptospiras can be demonstrated by the Fontana stain in fluids and by the Levaditi stain in tissues. If the interval between death and preservation of the tissues for the silver stain is prolonged, the organisms may disintegrate. Table 3 shows the laboratory data in 5 fatal cases. Although a high agglutinin titer is usually a good prognostic sign, 1 patient (A. T.) died even though the titer was 1:1,000,000.

CLINICAL DIAGNOSIS

In New Orleans leptospirosis must be suspected in a patient who presents the following picture:

1. Sudden onset of chills, fever, arthralgia, myalgia, injection of the conjunctiva, hemorrhagic phenomena, leukocytosis.
2. Hepatomegaly and jaundice appearing on the fifth to seventh day; but anicteric cases must be considered.
3. Albuminuria, casts, kidney failure with the retention of metabolites in the blood.
4. A history of exposure to rats or of coming into contact with water or food which is polluted with the excreta of rats and possibly of dogs.
5. The finding of leptospiras in the blood or urine and agglutinins in the serum of the patient.

TREATMENT

It is claimed that the specific treatment of leptospirosis consists in the administration of hyperimmune horse serum which must have an agglutinin titer of 1:1,000,000 against *Leptospira icterohemorrhagiae* and *Leptospira canicola*. The dose is 60 cc. (Inada²¹). Inada and his associates,² Griffith,²² Pettit and his associates,²³ Zimmermann and Arjona²⁴ and Walch-Sorgdrager²⁵ have shown that when the serum is used early in the disease the mortality is lowered. In Japan the mortality rate dropped from 30.6 to 18.3 per cent. In this country Gaines and Johnson²⁶ used 30 cc. of convalescent serum, and Ashe and his associates¹⁹ used 500 cc. of convalescent whole blood with good results. To be effective the convalescent serum must have a titer of 1:20,000. In the present series no hyperimmune horse serum was used. One patient received 250 cc. of convalescent whole blood in the fourth week of the disease, with no appreciable results.

All arsenicals are probably contraindicated, even though nearsphenamine has been used in some cases with questionable results.

Sazerac and Nakamura²⁷ used sodium bismuth tartrate intravenously in guinea pigs with favorable results. Uhlenhuth and Seiffert²⁸ used soluble colloidal bismuth chiniofon compound and reported good results. None of these drugs have been tried in the New Orleans series. Sulfonamides were administered in some of these cases, but they appeared to have no effect on the leptospiras. However, they are indicated when there is a bacterial complication.

Since hyperimmune horse serum and convalescent serum are not usually available and since the diagnosis of the disease is made late during the course of the infection, it is obvious that treatment must be symptomatic. The patients are given high carbohydrate, high protein and high vitamin diets to support the liver. Calcium gluconate is administered parenterally. The fluid intake of the patient must be adequate, so that fluids must be given by mouth, intravenously or by hypodermoclysis. Saline and dextrose infusions should be given frequently. When kidney failure becomes apparent the amount of dextrose must be increased, caffeine derivatives must be given in moderately large doses and hot applications or diathermy must be applied to the lumbar regions to encourage the secretion of urine. Mercurial diuretics are contraindicated. Small transfusions are helpful. Sedatives must be used when needed; cardiac tonics and stimulants are indicated when there is derangement of cardiac functions. During convalescence tonics, vitamins and iron should be administered.

PROPHYLAXIS

Wani²⁹ prepared a vaccine by treating emulsions of infected liver or cultures with 0.5 per cent phenol and refrigerating for seven days. Ten thousand two hundred and sixty-two miners were inoculated; they showed a morbidity of 0.3 per cent, while in the control, nonvaccinated, group the morbidity rate was 1.12 per cent. The serum of such persons protected guinea pigs against lethal doses of leptospiras. Van Thiel³⁰ used living avirulent strains of leptospiras which were maintained in cultures for eight years. He inoculated 5 persons with this strain. Four had atypical attacks, but the fifth manifested icterus. It is not advisable to use living leptospiras, since the factors which enhance the virulence of the organisms are not known. In the United States the disease is sporadic and there is no necessity for prophylactic inoculation.

SUMMARY

A clinical report on 30 cases of leptospirosis in Louisiana reveals that:

1. The incidence among the Charity Hospital inpatients from 1939 to 1943 was 1 case of leptospirosis to 8,445 general admissions and 1 case to 1,343 general medical admissions, while in 1943 it was 1 case to 5,263 general admissions and 1 to 760 general medical admissions.
2. Two patients had *L. canicola* infection.
3. The onset of the disease was sudden in two thirds of the cases, and icterus developed between the sixth and the seventh day after the onset of fever. Two patients were anicteric. The van den Bergh reaction was direct; the prothrombin time was prolonged, and hippuric acid excretion was reduced. In 10 per cent of the cases the liver was not enlarged even though jaundice was present. Splenomegaly was present in 10 per cent, hemorrhagic phenomena in 53.3 per cent and respiratory symptoms in 40 per cent of the cases. There was electrocardiographic evidence of cardiac lesions. All patients showed varying grades of pathologic changes in the kidneys, but 16 2/3 per cent had anuria, 80 per cent had albuminuria, casts, red and white blood cells, 10 per cent glycosuria and 83.4 per cent had leukocytosis. The phenolsulfonphthalein excretion

was reduced, and there was elevation of blood urea and creatinine. The duration of the disease was three to six weeks, and the mortality rate was 16 $\frac{2}{3}$ per cent.

4. Sixty-six per cent of the suspected cases of leptospiriosis were confirmed by laboratory methods. Seven cases (23.3 per cent) were diagnosed by the finding of leptospiras in the blood, 1 by their presence in the urine and 1 by their presence in the spinal fluid; in 2 fatal cases diagnosis was made by the Levaditi stain of sections of organs. In 24 cases (80 per cent) diagnosis was established by the agglutination reactions, in which the diagnostic titer ranged from 1:300 to 1:1,000,000.

5. The treatment was symptomatic, but 1 patient received 250 cc. of convalescent whole blood.

HYPERSENSITIVITY OF THE TUBERCULIN TYPE TO CRYSTALLINE PENICILLIN SODIUM

HENRY WELCH, PH.D.

AND

ADOLPH ROSTENBERG JR., M.D.

WASHINGTON, D. C.

In the limited number of reports that have appeared on the clinical use of penicillin sodium, urticaria seems to be the chief, if not the only, evidence of sensitivity to this drug. Keefer¹ reports 14 cases of urticaria out of 500 cases treated and Lyons² 12 cases of urticaria out of 209 treated. These reactions from commercial penicillin sodium, if predicated on a sensitization mechanism, are obviously not necessarily due to penicillin itself.

During the course of some studies designed to determine whether a correlation exists between the immediate local reactions obtained with certain lots of commercial penicillin sodium on intramuscular injection in man and those obtained by intracutaneous injection of the same material in rabbits and in man, a person, J. D. W., was injected intracutaneously in the left arm with four lots of commercial penicillin sodium representing the products of three different manufacturers. Each injection consisted of 0.05 cc. containing 1,000 units of penicillin. The subject had never been inoculated with penicillin previously but has worked with a variety of molds for the past fifteen years. Our investigations (about 200 intracutaneous injections in 12 people) indicate that most lots of penicillin sodium, on intracutaneous inoculation of 1,000 units dissolved in 0.1 cc. of water, produce within one to two hours an area of about 8 to 10 mm. of erythema and edema, while with some lots a small blister subsequently develops at the site of the inoculation. It therefore may be said that most commercial penicillin sodium is a mild primary irritant when injected intracutaneously. In contrast to this, crystalline penicillin has no primary irritating properties on intracutaneous injection, judging from 24 tests on 6 people. It is obvious, therefore, that the irritating properties of commercial penicillin sodium are from contaminants resulting as a by-product of its manufacture. None of the four skin tests in J. D. W. reacted during the first two hours. The first signs of a reaction occurred about six hours

after the intradermal tests had been made, at which time some redness and itching at the point of inoculation were noted. On observation twenty-four hours after injection, the erythematous areas had extended considerably and some infiltration was present. By the forty-eighth hour the points of inoculation had fused together into one large, erythematous, infiltrated, vesicular area. The reaction reached its peak between the forty-eighth and ninety-sixth hours, at which time the area measured 108 by 20 mm. and there was considerable exudation (fig. 1). Following the application of calamine lotion the area dried up, the superficial skin exfoliated and healing gradually took place.

Since commercial penicillin sodium is not a chemically pure compound it seemed possible that this person might be sensitive to some contaminating product resulting from the process of extraction. It is of interest that, of the three companies which produced the material injected into J. D. W., two produce penicillin by the deep tank process while the third uses the surface culture technic. All three companies use different methods of extraction.

In order to determine whether J. D. W.'s hypersensitivity was due to "penicillin" as such or to some contaminant resulting from the process of extraction,

Fig. 1—Ninety-six hours after the first four intradermal tests with commercial penicillin sodium

he was given two intracutaneous injections of penicillin in the right arm; one, the crystalline product (1,650 units per milligram) and the other a commercial product. The latter was produced by the surface culture technic. Both injections consisted of 1,000 units of penicillin contained in a volume of 0.05 cc. of water. At the same time, similar injections were made into two other persons as controls. Observations after one and two hours showed no reaction in any of these three individuals. The following day (approximately twenty-four hours later) the controls showed no reaction as a result of the injection of either the crystalline or the commercial penicillin sodium, but J. D. W. exhibited a definite reaction to both products. The areas were erythematous and infiltrated, and each measured 15 mm. in diameter. Within forty-eight hours the areas had increased to 30 mm. in diameter (figs. 2 and 3).

It should be pointed out that, although the crystalline penicillin sodium is for all practical purposes a pure product, there might be associated with it minute amounts of contaminating material resulting from the process of extraction and not eliminated in crystallization. The fact, however, that the reaction obtained by the intradermal injection of the crystalline material elicited a reaction of approximately the same intensity as that produced by the injection of the commercial

product would tend to obviate any minute amount of contaminating material as the primary cause of the reaction.

The course and clinical characteristics of the reaction exhibited to the intradermal injection of the penicillin had led us to believe that the hypersensitivity shown

Fig. 2—Twenty four hours after intradermal tests with commercial penicillin sodium

by J. D. W. was of the "tuberculin" variety. But in order to determine whether there was any eczematous component, it was decided to perform patch tests on him. Two patch tests with a few drops of commercial penicillin sodium (assaying 4,000 units per cubic centimeter) were performed. One test was applied to the site at which the crystalline penicillin sodium had previously been injected and the other to the upper arm in a previously uninjected area. The site at which the crystalline penicillin sodium had been injected had apparently completely healed except for a faint tinge of redness. The patches were removed after forty-eight hours, and the one which had been applied to the area where the crystalline penicillin had previously been injected showed a sharply delineated erythematous infiltrated area (fig. 4), whereas the patch applied to the upper arm was completely negative.

In order to elucidate this phenomenon further, four patch tests were then applied to the subject's left arm; two were of commercial penicillin sodium (4,000 units per cubic centimeter) and two of the corn steep liquor medium normally used for the production of penicillin. One with each substance was applied to areas where

Fig. 3—Forty-eight hours after intradermal tests with crystalline penicillin sodium

previous penicillin injections had been made, and one with each substance to areas where no previous penicillin injection had been made. The areas where the penicillin sodium had previously been injected were, at the time of patch testing, apparently healed except for a faint residual tinge of redness. In order to be sure that neither the penicillin sodium nor the corn steep liquor medium was a primary irritant, these

substances were applied as patch tests to 4 persons who had not exhibited any reaction to penicillin sodium on intradermal injection. All tests were removed and read at the end of forty-eight hours. The penicillin sodium applied to the previously penicillin injected area (J. D. W.) gave a reaction identical to the one that he exhibited to the same test on the other arm, previously described. The test with the corn steep liquor medium gave a weakly positive reaction consisting of erythema and very slight infiltration, but this was quantitatively much less than the reaction manifested by the penicillin sodium. After ninety-six hours the patch test to the penicillin sodium was still positive, whereas that to the corn steep liquor medium had faded out. The patch tests applied to the upper arms as well as the tests applied to the controls were completely negative.

The serum of J. D. W. was tested for precipitins against 8 samples of commercial and one of crystalline penicillin sodium. True precipitation was not demonstrated. Although with some samples of penicillin a fine precipitate developed, this type of precipitate was demonstrated also with normal serum and was probably due to a chemical contaminant of these samples.

Fig. 4—Forty eight hour appearance of patch test applied to site of previous injection of crystalline penicillin.

Heterophile agglutinins were demonstrated in low titer (1:16) in J. D. W.'s serum. Since these agglutinins could be removed completely by adsorption with guinea pig kidney and not by adsorption with rabbit erythrocytes, they were classified as native rather than serum sickness agglutinins.³

In order to determine whether it was possible to transfer the sensitivity shown by J. D. W. to animals, 0.5 cc. of his serum was injected intradermally into two areas on the clipped abdomen of two rabbits. At the same time two 0.5 cc. amounts of a normal serum, obtained from a person (G. G. S.) who had never been injected with penicillin, were injected similarly. In the first rabbit, twenty-four hours later, 1,000 units of crystalline penicillin sodium was injected into two of the areas previously injected with serum (one injection in the area injected with G. G. S.'s normal serum and one injected in the area inoculated with J. D. W.'s serum). In the remaining two areas, commercial penicillin sodium was injected similarly. The second rabbit, which had been treated with these two serums, was injected with penicillin sodium in exactly the same manner forty-eight hours after the injection of the

3 Stuart, C. A.; Welch, H.; Cunningham, J., and Burgess, A. M. Infectious Mononucleosis (Further Studies), Arch. Int. Med. 58:512 (Sept.) 1936

serum. Following injection of the penicillin, the rabbits were observed for a period of three days. At no time during this interval did a reaction occur in the skin. Passive transference experiments were attempted in man. Six persons were injected intradermally in separate sites with 0.1 cc. of J. D. W.'s serum, 0.1 cc. of a normal serum (from an individual who had never been exposed to penicillin and who, on skin testing with crystalline penicillin, exhibited no cutaneous reactivity) and at a third site with 0.1 cc. of crystalline penicillin sodium containing 1,000 units. Twenty-four hours later, at the site of the previous injection of serums (both J. D. W.'s and control), 1,000 units of crystalline penicillin sodium in a volume of 0.1 cc. was injected. These six persons were kept under observation for three quarters of an hour and no reaction developed during this time or within the next twenty-four hours. Two of the subjects, however, C. W. P. and V. C., both of whom had had a number of previous intradermal injections of commercial penicillin sodium, showed reactions (erythema plus itching) at the site of these injections.

COMMENT

From a study of the reactions given by J. D. W. it appears that this person's hypersensitivity is definitely of the tuberculin type. Our reasons for stating this are (a) the lack of any immediate reaction to the intradermal injection of the material, (b) the fact that the reactions first became manifest approximately six hours after the intradermal introduction of the allergen and reached a maximum between twenty-four and forty-eight hours, (c) the fact that the reaction clinically consisted first of erythema, then infiltration and subsequently exudation, (d) the lack of demonstrable anaphylactic antibodies as evidenced by the negative precipitin tests and (e) the lack of demonstrable passive transference antibodies as evidenced by the failure to transfer the sensitivity to human volunteers.

It should be emphasized that as far as we were able to determine this person's sensitivity was to pure crystalline penicillin sodium. The crystalline material used was a portion of the master standard which has been established by the Food and Drug Administration for the assay of penicillin and as far as is known is a definite crystalline entity.

We are unable to state unequivocally the meaning of the positive patch test. Although clinically the reaction was of an eczematous nature and consonant with that seen in an eczematous hypersensitivity, it is difficult to explain the negative patch tests in J. D. W. when applied to normal skin. As far as we can see, the reason for the lack of reaction on the part of the normal skin could have been from one of two causes: (a) the eczematous hypersensitivity did not exist except in the areas that had previously been injected with penicillin or (b) the normal skin was less permeable than the areas that had previously been injected, so that the penicillin could not get to the eczematogenous shock tissue. It is possible, of course, that the positive patch test result in the lower arm was in a sense pseudo-positive in that it was not a reaction on the part of a hypersensitive epidermis but a reaction of the cells of the reticuloendothelial system in the cutis brought about by the transepidermal penetration of the allergen or, in other words, another demonstration of this individual's tuberculin type of sensitivity.

Ordinarily the tuberculin type of hypersensitivity indicates that the individual has had exposure to the

living agent. J. D. W. gives no history of an illness which we could reasonably state was due to *Penicillium* sp., but this man has been intimately exposed to molds of various kinds for the past fifteen years, so that it is not too unreasonable to assume that he has had a subclinical infection with *Penicillium* sp. or an immunologically related fungus, which has caused this alteration in his immune responses.

Preliminary unpublished observations in this laboratory indicate that various sensitization phenomena may develop fairly readily to penicillin in both man and animals. The experience with J. D. W. and these facts suggest that penicillin should be handled with caution, especially in its commercial production, in which intimate contact with large volumes of this drug and great numbers of spores cannot be avoided.⁴

SUMMARY AND CONCLUSIONS

1. A person was observed who exhibits a tuberculin type of hypersensitivity to crystalline penicillin sodium. The man had no prior exposure to penicillin.
2. However, he has had intimate contact with molds over a period of years.
3. The significance of such a hypersensitivity when the drug is to be used therapeutically is unknown.

PENICILLIN IN THE TREATMENT OF CAVERNOUS SINUS THROMBO- PHLEBITIS

RECOVERY WITH UNILATERAL ASCENDING OPTIC ATROPHY

W. M. NICHOLSON, M.D.

AND

W. B. ANDERSON, M.D.

DURHAM, N. C.

Until the advent of the sulfonamides cavernous sinus thrombosis or thrombophlebitis, infected with the staphylococcus, was universally fatal, but several instances of recovery under sulfonamide treatments have been reported.

We shall report in this paper an instance of cavernous sinus thrombosis, with staphylococcal septicemia, which was successfully treated with penicillin.

A detailed anatomic description of the cavernous sinuses and the clinical significance of their tributaries is contained in a paper by Grove.¹ According to this author, when a thrombophlebitis of the facial vein develops as a result of the injudicious incision of a furuncle of the upper lip, or the extraction of a hair from an infected follicle of the brow or nares, and this thrombophlebitis extends through the angular and ophthalmic veins to the cavernous sinus (the anterior route) the mortality is 100 per cent. Statistical studies, gathered from previous reports, which included cavernous sinus thrombosis as an extension of the thrombophlebitis from the lateral or the pterygoid sinuses, reveals a mortality of 90 per cent.

4. Since submission of this article a study of 140 unexposed persons indicates that approximately 5 per cent exhibit a tuberculin type of reaction to the initial injection of crystalline penicillin sodium.

From the Departments of Medicine and Surgery, Duke Hospital and Medical School.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutic and Other Agents of the National Research Council.

1. Grove, W. E.: *Septic and Aseptic Types of Thrombosis of the Cavernous Sinus*, Arch. Otolaryng. 24: 29 (July) 1936.

In 8 instances of cavernous sinus thrombosis studied at Duke Hospital, including 1 in which 10,000 units of penicillin was administered intravenously and 15,000 units by continuous intravenous drip during the twenty-four hour hospital stay, all the patients died. As late as 1937, MacNeal and Cavallo² could find records of only seven reported recoveries from acute thrombosis of the cavernous sinus.

However, the Wolfes³ report a recovery from an anterior focus (infected hair follicle) through the use of sulfathiazole.

Skemp, Afrenow and Rhoads⁴ also report a recovery from an anterior focus (infected hair follicle of brow) due to the use of sulfathiazole (149 Gm. in twenty-three days, at one time 21 Gm. per day). Schall⁵ cites three recoveries due to the use of sulfonamides by Barnshaw, Seydell and Pace.

The case here reported is of especial interest, particularly to ophthalmologists, in that we were able to observe the obliteration of branches of the retinal artery in association with engorgement of the retinal veins and a rapid atrophy of the optic nerve.

REPORT OF CASE

History.—A white farmer aged 30 was admitted on Oct. 31, 1943 in a semicomatose condition. Four days before admission he noticed a small furuncle in the right external naris. The following afternoon he received a smart blow across the bridge of his nose and later in the evening developed a severe pain in this area and severe bifrontal headache. The next morning, two days before admission, he had a hard chill, which was followed by high fever. At this time periorbital edema was apparent, and during the day it progressed to such an extent that he could not open his eyes. Thick yellow pus exuded from the right eye. The edema and redness extended from the bridge of the nose up over both frontal areas and down across both maxillae. The patient was given sulfadiazine while at home, in spite of which he continued to have chills and fever. On the morning of admission he became stuporous and could be aroused only by painful stimuli.

On admission, three days after onset, he presented the picture of an extremely ill person lying quietly in bed in a semicomatose state. There was bilateral exophthalmos with a pronounced swelling of the lids. The right upper lid could not be voluntarily retracted; the left could be retracted partially. A brawny, deep reddish purple swelling extended from below the mandible over the nose and cheeks well up to the hair line. The nose was remarkably swollen, being enlarged to more than twice its normal size (fig. 1). There was local elevation of temperature and much tenderness over the entire area. The right side of the face in all respects showed greater involvement than the left. The conjunctiva of the right eye was chemotic, the right eye more proptose than the left. Movement of the right eye was limited, but no paralysis was noted at this time. There was no involvement of the fundi at this stage of the disease.

The lungs were clear both to physical and to x-ray examination. Save for a loud systolic murmur over the apical region, the heart was normal. The remainder of the examination revealed nothing of interest.

Laboratory Studies.—Blood Kahn and Kline reactions were negative. Blood examination revealed 5,150,000 red blood cells, hemoglobin 160 Gm., 30,600 white blood cells, of which 89 per cent were segmented polymorphonuclears, 0 per cent stab cells, 0 per cent young forms, 0 per cent eosinophils, 0 per cent basophils, 1 per cent mononuclears, 5 per cent large lymphocytes and 5 per cent small lymphocytes.

Blood cultures on October 31 yielded two colonies of hemolytic *Staphylococcus aureus* per cubic centimeter, November 3 less than one colony of hemolytic *Staphylococcus aureus* per cubic centimeter, and November 5, 7 and 9 no growth.

In the urine November 1 albumin was 1 plus, and there was an occasional red blood cell and white blood cell in the sediment. November 6 there was a trace of albumin and an occasional red blood cell. Subsequent examinations of the urine gave normal results.

Course in the Hospital.—The patient had been given sulfadiazine before admission, and the concentration of sulfadiazine in the blood was 7.5 mg. per hundred cubic centimeters. During the next twelve hours he was given 3 Gm. of sulfadiazine intravenously and 4 Gm. by mouth, but despite this his condition grew worse. The edema and induration became so great as to make fundus examination impossible. It was decided that penicillin should be given, and he then received 10,000 units intravenously and 5,000 units subcutaneously. No further intravenous administration of the material was given, but the subcutaneous route was used throughout his hospital stay in dosages

Fig. 1.—Appearance of the patient three days after admission to the hospital. The face, eyelids and nose are edematous.

as shown in the chart (fig. 4). Since the differential showed a predominance of segmented forms of polymorphonuclear cells, staphylococcus antitoxin was not given.

No change in his condition was apparent until six days after admission, at which time he became rational and responded to questions. The swelling of his face was less, and the temperature had fallen considerably. He complained bitterly of a frontal headache, which was somewhat worse on the right.

His course from that time was one of steady improvement. By the fourteenth hospital day penicillin was discontinued, as the patient had been afebrile for twenty-four hours. However, on the nineteenth hospital day his temperature had risen to 38.5 C. (101.5 F.) and the headache, which had improved somewhat, became more severe. Penicillin was again given and continued for eight days. After two days he was relieved of his headache entirely, became afebrile, and his improvement became more pronounced. On the tenth day the swelling had subsided sufficiently to permit the use of the left eye. On the twelfth day the left lid was practically normal, the right still greatly swollen. On the twenty-second day of illness the right lid could be partially elevated. It was then discovered that vision in the right eye was limited to light perception.

On the twenty-sixth day of the illness the sensorium had cleared and the condition of the patient was such as to permit a satisfactory ophthalmologic examination. Vision of the right eye was reduced to light perception. The left eye was apparently normal. The upper and lower lids were both puffy, the epider-

Fig. 2.—Appearance at discharge from the hospital. There is still brawny edema over the bridge of the nose, pronounced dilatation of small veins over the nose, and ptosis of the right lid.

mis glazed and cracked and discolored a dusky brownish red. There was considerable bulbar chemosis bilaterally, the right being more pronounced than the left. The pupils were regular and equal and reacted to light. There was bilateral limitation of upward motion. The intraocular tension was not recorded. Ophthalmoscopic examination of the left fundus revealed a normal disk, macula and vascular tree. The right disk showed

Fig. 3.—Right fundus five months after onset. The arteries are constricted; there is also retinal edema.

moderate swelling, with engorgement of the retinal veins and partial collapse of the arterial bed. There was a diffuse retinal edema, the macula being sharply outlined but not having the cherry red color suggesting occlusion of the central retinal artery. One received the impression, nevertheless, that the retinal edema and the accentuated macula were the result of

ischemia, secondary to the collapse of the arterial tree, the expression collapse being here used as best describing the appearance of the arteries. The inferior temporal artery also showed extensive perivascular sheathing, as did the other branches though to a lesser degree.

The patient was discharged from the hospital after thirty-eight days. There was total loss of vision in the right eye. Sight in the left eye was unimpaired. Otherwise there were no symptoms. Slight edema of the upper part of the face persisted, particularly over the right orbit and the bridge of the nose. Also over the nose small dilated veins could be seen (fig. 2). There was a paresis of the right superior rectus and a ptosis of the right lid. The fundi remained as described.

On Feb. 17, 1944, sixty-one days after discharge, the patient returned to the clinic. The small veins (the inferior palpebral arcade) beneath both eyes were considerably dilated, with some fullness of the veins over the temporal area. There was occasional frontal headache. Vision in the right eye remained limited to light perception.

The optic fundi were examined in detail. The left was normal. The right disk was slightly elevated. A pronounced pallor was already apparent. The sheathing of the arteries

Fig. 4.—Temperature, white blood cells and penicillin therapy while patient was in the hospital.

noted previously was not so apparent but was present to an abnormal degree. The arterial bed was more constricted near the disk than in the areas between the first and second bifurcations. The macula reflex was normal. Retinal edema was not apparent with the ophthalmoscope but could be demonstrated by fundus photography.

The physical examination on this date was otherwise negative. The patient returned on March 21, approximately three months after discharge. Collateral superficial circulation about the lower lids in association with the temporal veins was more apparent. The bridge of the nose, the malar eminences and the median portion of the forehead appeared as a red mask, and slight magnification revealed a tremendous number of dilated interlacing venules.

The left fundus was again found to be normal; vision 20/20. Vision in the right eye was limited to light perception. The disk showed great pallor with minimal gliosis. The macula appeared normal and the veins appeared normal in size and color. The arteries continued to show the great constriction noted previously. The perivascular sheathing of the arteries was not so prominent but was present. The arteries continued to show the greater constriction near the disk. Figure 3 is a fundus photograph on this date showing this abnormality in the caliber of the arterial tree. Some retinal edema still persisted.

COMMENT

Two questions arise:

1. Was the diagnosis correct?
2. What is the explanation for the constriction of the arterial tree and the optic atrophy?

As proof of the accuracy of the diagnosis in this case (1) there is the history of the furuncle in the lateral nasal wall with the secondary insult resulting from the sharp blow over the nasal bridge; (2) after a short incubation period there is the onset of general malaise, chills and increased temperature; (3) there is the definite bacteremia, staphylococci being recovered on two occasions from the blood stream; (4) there is the bilateral exophthalmos, chemosis of the conjunctiva, edema of the face and dusky red discoloration of the skin as evidence of venous obstruction and, finally, there is (5) the profound stupor.

The increased perivascular sheathing of the proximal portions of the retinal artery, with constriction in these portions, and papilledema followed by secondary atrophy is difficult to explain. As a matter of fact no thoroughly satisfactory explanation has been offered as to why cavernous sinus thrombosis, proved at autopsy, can occur without papilledema. The explanation that the central retinal vein may empty into one of the ophthalmic veins rather than the cavernous sinus seems inadequate. The elder Stocker in 1906 suggested that papilledema in cavernous sinus thrombosis is uncommon because the arterial pressure in the eye is, at least in some cases, reduced by the increase in venous pressure coincident with the venous obstruction. In this particular case we feel that there was impediment to the arterial circulation, definitely more than would be expected by the relatively mild papilledema. The sheathing of the arteries suggested an inflammatory reaction in the arterial wall. This inflammatory reaction could have extended directly along the artery from the sinus, since it is here that the artery comes in closest contact with the infected focus; or the apparent inflammatory reaction, with constriction most pronounced in the proximal portions of the arterial tree, may have been due to the irritation of the sympathetic plexus in the carotid sheath in the sinus.

In any case it is probable that the atrophy was secondary to embarrassment of the arterial circulation with ischemia and later edema of the retina; in other words, an ascending degeneration.

CONCLUSIONS

The efficacy of penicillin as a therapeutic agent is further demonstrated when used in cavernous sinus thrombosis.

Optic atrophy, resulting from cavernous sinus thrombosis, may be the result of an ascending degeneration secondary to constriction in the central retinal artery with ischemia of the retina, due either to arteritis or to irritation of the sympathetic plexus in the sinus

Founder of British Dermatology.—Robert Willan (1757-1812) of London is the accepted founder of British dermatology, who marks the beginning of modern dermatology. In 1785 he presented a plan for the classification of skin diseases before the Medical Society of London, which five years later was given the Fothergillian medal; Jenner received the same medal a few years later—Pusey, William Allen. *The History of Dermatology*, Springfield, Ill., Charles C Thomas, 1933

NONSPECIFIC MAJOR OPERATIONS AND
LUMBODORSAL SYMPATHECTOMYA COMPARISON BETWEEN THEIR EFFECTS ON
THE BLOOD PRESSURE

FRANCISCO ROJAS, M.D.

SANTIAGO, CHILE

R H SMITHWICK, M.D.

AND

PAUL D. WHITE, M.D.

BOSTON

The surgical treatment of hypertension by sympathetic resection has met many objections in the last few years. One of these concerns the specific value of sympathectomy in the reduction of blood pressure in the patients who have undergone operation.

In 1939 Volini and Flaxman¹ followed the course of the blood pressure of 17 hypertensive patients oper-

TABLE 1—General Data

TABLE 2—Immediate Effect of Operation

	No Results	Moderate Reduction	Pronounced Reduction
Group 1 Immediate reduction (up to 6 months after the operation)			
Systolic pressure	49%	49%	2%
Diastolic pressure	60 3%	27 1%	12 6%
Group 2 Immediate reduction (10 days after the second stage of the operation)			
Systolic pressure	3 3%	24 4%	72 3%
Diastolic pressure	8 5%	37 7%	53 5%

ated on for different reasons not related to their hypertension. They observed in almost every case a decided reduction of the blood pressure after the operation. They arrived at the conclusion that the blood pressure reduction attributed to nerve resection was actually due to the general conditions to which every patient who is operated on is subjected: bed rest, anesthesia, sedatives, operative shock and special diet. On these bases they denied the specific effect of sympathetic nerve resection on hypertension.

In September 1943 Adamson and Dubo² arrived at a similar conclusion. Following the course of the blood pressure of 58 hypertensive patients submitted to various major operations during eight to ten days after the operation was performed, they observed a reduction of the systolic blood pressure, which was, on the average, 29 per cent of the blood pressure prior to the operation. Comparing this figure with the 28 per cent of systolic blood pressure reduction reported by

Read before the New England Heart Association, Jan. 31, 1944.

2. Adamson, J. D., and Dubo, S.: The Effect of Surgical Operations on Blood Pressure, *Canad. M. A. J.* 49: 161-166, 1943.

Crile³ after celiac ganglionectomy, they concluded, as Volini and Flaxman had done, that the results of sympathetic operations are not specific and can be observed after any major operation.

With the purpose of checking these opinions, we have reviewed the records of hypertensive patients admitted

TABLE 3.—Condition Six or More Months Later

	No Results	Moderate Reduction	Pronounced Reduction
Group 1. Late reduction (more than 6 months after the operation; average period of observation, 10 months)			
Systolic pressure.....	82.7%	17.3%	0%
Diastolic pressure.....	86%	14%	0%
Group 2. Late reduction (more than 12 months after the second stage of the operation; average period of observation, 20 months)			
Systolic pressure.....	9.6%	28.1%	62.3%
Diastolic pressure.....	7.6%	36.1%	56.3%

to the Massachusetts General Hospital during the last ten years who were submitted to different major operations, in particular hysterectomy, mastectomy, gastrectomy and thyroidectomy. We have studied 100 cases in which the blood pressure readings were adequate for our purpose.

On the other hand, we have studied the reduction of blood pressure in 100 hypersensitive patients submitted to bilateral lumbodorsal sympathectomy by the procedure of Smithwick,⁴ performed in two stages but otherwise unselected. Some of these records were taken from the files of the Massachusetts General Hospital, and others from the private files of one of us (R. H. S.). The general data concerning the patients are summarized in table 1.

We have summarized in table 2 the immediate effect that the operations had in both groups. We have considered as "no results" reductions of less than 5 per cent of the initial systolic or diastolic blood pressure, "moderate" the reductions between 5 and 25 per cent and "pronounced" the reductions over 25 per cent of the blood pressure prior to the operation. As shown in table 2, even the immediate reduction of blood pressure is quite different in the nonspecific and the specific operation groups. Six or more months later this difference is still more evident, as summarized in table 3.

TABLE 4.—Reduction of Blood Pressure After First Stage and After Second Stage of Lumbodorsal Sympathectomy

	No Results	Moderate Reduction	Pronounced Reduction
Results 10 days after first stage of lumbodorsal sympathectomy			
Systolic pressure.....	30%	64%	6%
Diastolic pressure.....	42%	44%	14%
Results 10 days after second stage of lumbodorsal sympathectomy			
Systolic pressure.....	3.3%	24.4%	72.3%
Diastolic pressure.....	8.8%	37.7%	53.5%

We have also made a comparison of the reduction of blood pressure observed after the first stage with that after the second stage of lumbodorsal sympathectomy. The first stage of this operation can be considered like any major operation. It lasts one to one

and a half hours and is performed under general anesthesia. If the sympathetic resection has no specific effects, there should be no reason for a difference between the two stages of the operation. We have summarized in table 4 the results of this comparison.

Observing the figures in table 4, it is reasonable to conclude that the blood pressure reduction obtained by the first stage of lumbodorsal sympathectomy is quite similar to that observed after any other operation. It is not until the second stage is performed that a real reduction of blood pressure is observed.

As a final indication of the specificity of the sympathetic operation, we have summarized in table 5 the

blood pressure data of a certain number of patients who have had, in addition to the lumbodorsal sympathectomy, another operation performed before or in the interval between the two stages of the sympathectomy.

SUMMARY AND CONCLUSIONS

This study has shown that nonspecific major operations, as studied in 100 patients, produce some immediate reduction of the blood pressure of hypertensive patients, as has been reported in previous papers. However, this reduction is not pronounced and in the great majority of cases persists for only a short time. On the contrary, lumbodorsal sympathectomy by Smithwick's technic, as studied in a second group of 100 cases, produces in the majority a pronounced reduction of

blood pressure which is still present after a considerable period of observation. The specificity of this operation is also demonstrated by the fact that definite results are not observed until after the second stage operation has been performed, the first stage producing about the same effect as any other major operation. Finally, the fact that in patients in whom major operations were performed in addition to lumbodorsal sympathectomy a pronounced and lasting reduction of blood pressure is not observed until the sympathetic resection is performed is further evidence of the fact that lumbodorsal sympathectomy has a specific effect in reducing blood pressure.

Massachusetts General Hospital

INFECTIOUS HEPATITIS IN THE MIDDLE EAST

A CLINICAL REVIEW OF 200 CASES SEEN IN A MILITARY HOSPITAL

CAPTAIN WALTER P. HAVENS JR

MEDICAL CORPS, ARMY OF THE UNITED STATES

Within the past two or three years infectious hepatitis has become recognized as an epidemic disease of increasing military importance.¹ Its prevalence among British troops in the Middle East has been high,² but it has not been limited to British forces or to that particular geographic area, for this disease has occurred in the armies of other allied nations; in the French army in Tunisia,³ in the Italian army in Sicily in 1941⁴ and in the German army⁵ as well as in the civilian population of Palestine.⁶ Outbreaks of what may be the same disease have also occurred in the civilian population of Scandinavia,⁷ England⁸ and America,⁹ but in the absence of diagnostic tests the relationship of infectious jaundice to so-called catarrhal jaundice¹⁰ as well as to various types of "epidemic jaundice"

(with the exceptions of yellow fever and Weil's disease) is not clear.¹¹ Furthermore, the question has arisen as to whether the types of hepatitis following the inoculation of human serum¹² (icterogenic serum) and yellow fever vaccine¹³ are the same and thus represent artificial examples of infectious hepatitis. In view of these obscurities, it will not be the function of this paper to review the literature or to consider the pathogenesis and epidemiology of infectious hepatitis. My object in the present report has been to assemble data on the clinical picture of this disease as seen in a group of patients diagnosed as having infectious hepatitis (and infectious cholangitis) at an American military hospital in the Middle East during the years of 1942 and 1943.

CLINICAL MATERIAL AND METHODS

The patients described in this paper had contracted their disease in various sections of the Middle East, North Africa and the eastern Mediterranean area including Sicily and Italy. In these areas the disease had been endemic in British and American troops throughout the year, but there was a sharp rise in prevalence beginning in late October and receding during the winter months. Actual dates of admission to the hospital by months appear in chart 1.

For the clinical analyses the pertinent data were assembled from 200 hospital case histories on a master chart. All histories were included from patients on whom the diagnosis of infectious hepatitis (or infectious cholangitis) was made during the period of Nov. 11, 1942 to Feb. 1, 1944. For purposes of convenience and clarity of description the clinical course of the disease was divided when possible into two phases: the preicteric phase, starting with the onset of symptoms, and the icteric phase, starting with the time when the patient first noticed that his urine was dark and terminating when the serum icterus index reached approximately normal levels.

A definite preicteric phase was presented by 167 (83.5 per cent) of 200 patients, while the remaining 33 patients (16.5 per cent) presented jaundice as the first complaint without any preceding symptoms. The latter group was included in the description of the icteric phase. All patients were men of an average age of 25.5 years, ranging individually from 19 to 52 years, although there were only 3 who were older than 40 years of age.

From the Medical Division, General Hospital
Assistance in the collection of clinical material was given by the following medical officers: Lieut. Col Robert B. Nye, M. C.; Major Edgar Deesen, M. C., Capt Edward Tallant, M. C., Capt Albert Maisel, M. C., and Capt John Stone, M. C.

This work was carried out under the direction of the Medical Service, Office of the Surgeon General, U. S. Army

CLINICAL COURSE OF THE DISEASE

In chart 2 a diagram has been composed to show the clinical picture of a typical average case of the disease which is to be described in this paper. The preicteric phase, when present, ranged in length from one to eighteen days, with an average of five days, and mani-

Chart 1.—Seasonal variation in the admission rate of American troops with infectious hepatitis to an American general hospital in the Middle East from Nov. 11, 1942 to Feb. 1, 1944.

festated all grades of severity from the mildly sick to the severely prostrated patient.

The most common symptom in the preicteric phase of the disease was anorexia, which began insidiously and which was usually the first complaint. This early loss of appetite was particularly noticeable in the field, where rations were monotonous, and such early aversion to food was often observed by the group medical officer as beginning evidence of disease before the patient felt actually sick. Nausea soon became evident after meals, and although vomiting was less common it frequently occurred later in the preicteric phase just before the onset of jaundice. In the ensuing few days many men complained of weakness and described it as lack of energy to perform duty and disinterest in work. Members of the Air Force in particular noted lack of

sensation in the left upper quadrant. Palpation of the upper abdomen in these cases in the preicteric phase frequently elicited tenderness, although rarely was the liver or spleen palpable. Disorders of bowel function were not common; constipation occurred more frequently than diarrhea.

In approximately one half of the 167 patients manifesting a preicteric phase, the onset was sudden with frank chill or chilliness, fever, malaise, headache and generalized aches and pains. In general the temperature was remittent, with a daily peak of 102 F. declining gradually to normal in the course of five days, although not infrequently daily chill with elevation of temperature to 103-104 F., followed by return to normal, was encountered during the first two to three days (chart 2). These patients were often prostrated and complained of aching eyes and occasionally pain on motion of the eyeballs. A certain number of patients had evidence of inflammation of the upper respiratory tract coincident with the onset of disease. As in the afebrile cases, anorexia, nausea, vomiting and upper abdominal distress developed early in the course of disease. Clinical jaundice appeared twenty-four to forty-eight hours after the temperature reached normal.

interest in flying. Upper abdominal discomfort developed early and was reported as a sense of fulness and aching in the epigastrium and right upper quadrant, particularly evident after eating and occasionally associated with flatulence. Activity or jolting the body usually intensified this discomfort. Occasional patients complained of a sense of tightness and a dragging

Such patients constituted problems in differential diagnosis, and they were usually admitted with the diagnosis of fever of unknown origin. Malaria and, during the early Autumn, sandfly fever were the two diseases most frequently considered. The repeated chills with high fever associated with nausea and vomiting suggested malaria, while the headache, pain in the eyes and discomfort in the eyeballs on motion associated with pyrexia simulated sandfly fever. In such a clinical picture the presence of anorexia was a most important guide to the diagnosis of infectious hepatitis. Later in the preicteric state tenderness over the liver and the appearance of bile in the urine established the diagnosis. The importance of biluria cannot be overemphasized, and daily gross examination of the urine by the medical officer himself for bile did much to establish early diagnosis before clinical jaundice was evident.

An analysis of symptoms in order of their importance appears in table 1.

The icteric phase varied in severity and length from four to eighty-three days, with an average duration of twenty-seven days. Other patients have been observed, however, in whom jaundice lasted one hundred and twenty days (chart 3).

The presence of bile in the urine was the earliest and most frequent sign of developing icterus and usually

preceded the appearance of clinical jaundice by forty-eight to seventy-two hours.

Fever was almost always absent in this phase. Anorexia, nausea, vomiting and epigastric discomfort persisted for two to thirty days in varying degrees of severity, with an average duration of nine to ten days. In the mildest cases these symptoms were slight. However, in the severely sick patients symptoms at times persisted as long as a month. As the jaundice increased the pigment diminished in the stools, and acholic stools commonly occurred in the sicker patients. Constipation was often associated with this and diarrhea occasionally. Such general cholemic symptoms as lassitude, mental irritability and depression were present in a small number of patients. Itching was not common, but at times it was intractable. Occasional patients were seen with severe lacerations of the skin due to scratching. Bradycardia was uncommon and appeared in the first two weeks of jaundice, lasting from five to twelve days but averaging seven days in duration. However, a pulse rate of 60 to 70 was common throughout the period of jaundice when patients were at rest.

Physical examination revealed enlargement of the liver in 58.5 per cent of patients by the time jaundice

Occasional patients⁶ in this series had such mild disease that clinical jaundice was never evident. The presence of the characteristic symptoms with mild tenderness in the right upper quadrant and epigastrium, bile in the urine and elevation of the serum icterus index as high as 12 to 18 units, occurring in patients

was evident. The edge of the liver was firm and palpable 1 to 2 fingerbreadths below the costal border. While enlargement and tenderness of the liver did not always coincide, both were present in 43 per cent of patients. In general, tenderness subsided in nine to ten days, although it occasionally persisted as long as three weeks. Enlargement of the liver lasted from seven to thirty-three days, with an average duration of twelve days. Epigastric tenderness and distention were often associated, and clinical evidence of pylorospasm with dilatation of the stomach was occasionally present. Vomiting of copious quantities of undigested food and liquids afforded temporary relief. Enlargement and tenderness of the spleen occurred in a small number of patients. These signs and symptoms ordinarily persisted for seven to fifteen days after the appearance of jaundice, diminishing rapidly after the icterus reached its height. Continuation of epigastric discomfort and tender enlarged liver were regarded as signs of persistence of activity of disease.

It has been previously pointed out that mild forms of this disease without clinically evident icterus have occurred among outbreaks of frank jaundice.¹⁴

from groups in which infectious hepatitis was present, suggested the diagnosis of infectious hepatitis without clinical jaundice.

An analysis of signs and symptoms of the icteric phase in order of their importance appears in table 2.

After the icterus reached its height, which generally occurred by the tenth day of jaundice, the symptoms regressed and a sense of well-being returned. Pigment reappeared in the stool in increasing amounts. By this time it was not uncommon for patients to have lost 5 to 10 pounds (2.3 to 4.5 Kg.) and many of them had a ravenous appetite. Strength returned rather quickly in the mild and moderately sick patients. It was observed, however, that activity not uncommonly caused a sense of fullness and discomfort in the abdomen for several days after the patient felt well otherwise. Jaundice faded slowly and patients were kept in the hospital until their icterus index was normal. Most of those who had had mild or moderately severe disease were fit for duty at this time, but those who had been severely sick often required ten days' sick leave. Hospitalization of the entire group ranged from seven to eighty-seven days, with an average length of 29.8 days.

Occasionally the course of disease was more severe in the older patients and recuperation more prolonged. In an effort to correlate the severity and duration of jaundice with the age of the patient it was shown that the greater number, 167 (73.5 per cent), fell in the

TABLE 3.—Relation of Age to Duration of Jaundice

decade between 19 and 29. The remaining 33 patients (26.5 per cent) were between 30 and 39 years of age with the exception of 3 (48, 51 and 52 respectively).

Table 3 shows the relation of age to duration of jaundice.

Complications.—The only complication observed in this series was seborrheic dermatitis, which occurred in many patients during the icteric phase. Ascites was not observed in any patient.

14. Cameron, J. D. S.: Infective Hepatitis, *Quart. J. Med.* 12: 139 (July) 1943.

Relapse.—Of 200 patients in this series 3 had a relapse during their course of disease, manifest by an increase in jaundice and exacerbation of symptoms but without fever. The average duration of jaundice in these patients including the relapse was forty-nine days, with an individual variation from forty-three to fifty-eight days. Other patients have been observed who have had fever associated with the onset of a relapse.

It was difficult to associate the occurrence of a relapse with anything in particular. One of the aforementioned patients had received 122 Gm. of sulfaguanidine for bacillary dysentery early in the course of jaundice, given four weeks before the occurrence of the relapse. Another patient not included in this group had a secondary rise in the icterus index after receiving carbarsone in the treatment of amebiasis found incidentally during the course of jaundice.

In individual cases it seemed at times as though overexposure or excessive activity induced an increase in jaundice; however, such occurrences also took place

without preceding overactivity and did not appear to be related to any specific stimulus.

Antisyphilitic Therapy.—It is already recognized that the prevalence of infectious hepatitis is far higher in patients undergoing antisyphilitic therapy.¹⁵ In this group 6 patients had received antisyphilitic therapy in the form of neoarsphenamine, mapharsen or bismuth within three months before onset of jaundice. In these

who had gradually increasing icterus lasting as long as thirty-one days before the peak was reached.

Curves drawn to show the severity and duration of jaundice revealed considerable variation. These variations (based on tests for 180 patients) have been divided into four groups according to the duration of jaundice (chart 4).

GROUP 1.—Sixty-four patients (32 per cent) had jaundice varying from four to nineteen days and constituted examples of mild disease. While the serum icterus index in some of these patients reached as high as 60 units, a few had jaundice of such slight degree that it was not demonstrable clinically.

Case 1 represents a mild case of infectious hepatitis in which jaundice was not evident clinically and its detection was dependent on the icterus index determination and the presence of bile in the urine:

An enlisted white man aged 24 was admitted to the hospital with the chief complaint of nausea, vomiting and diarrhea. The patient was well developed and nourished and was dehydrated. His temperature was 99 F., pulse rate 80 and respiratory rate 20. No icterus was evident. The heart and lungs were normal. There was slight tenderness in the right lower quadrant. The liver and spleen were not felt. On the third day of disease the leukocytes numbered 7,700, with 65 per cent polymorphonuclear cells, 32 per cent lymphocytes, 1 per cent monocytes and 2 per cent basophils. Urinalysis showed albumin 1 plus and bile present in the urine with urobilinogen positive in a dilution of 1:200. The icterus index measured 18 units. The blood Kahn reaction was negative.

His recovery was uneventful and rapid. The nausea and vomiting disappeared after five days. The icterus index was at its maximum, 18 units, on the third day of disease and diminished to normal in the course of the next ten days.

GROUP 2.—Ninety-eight patients (49 per cent) had jaundice lasting twenty to thirty-nine days and made up the group having moderately severe disease. The serum icterus index very often ranged as high as 80 to 90 units.

CASE 2.—A medical officer aged 22 was admitted on Jan. 26, 1943 with the chief complaint of dark urine of four days' duration. Eight days before admission he had a sudden onset with chills, fever and anorexia, generalized aches and pains, with headache and pain in the eyes on motion. Clinical jaundice became evident two days before admission.

The patient was well developed and nourished. He was jaundiced but did not appear sick. His temperature was 98.6 F., pulse rate 88 and respiratory rate 18. Examination was essentially negative except that the liver was tender and palpable 1 fingerbreadth below the costal border. The erythrocytes numbered 4,240,000, hemoglobin was 85 per cent and leukocytes numbered 4,650, with 65 per cent polymorphonuclear cells, 20 per cent lymphocytes, 8 per cent monocytes and 1 per cent basophils. The serum icterus index measured 54 units. The blood Kahn reaction was negative. Urinalysis revealed bile and albumin 3 plus. The icterus index reached its height of 72 units on the tenth day of the disease and receded over the next eleven days to normal. Anorexia and tenderness of the liver subsided shortly after the jaundice reached its height, and recovery was uneventful.

GROUP 3.—Thirty-eight patients (19 per cent) had jaundice lasting from forty to eighty-three days, constituting the group with severe disease. The icterus index was as high as 149 units in an occasional patient.

Case 3 represented a severe case of infectious hepatitis, prolonged over a period of eighty-three days:

CASE 3.—An enlisted man aged 22 was admitted to the hospital Aug. 15, 1943 with the chief complaint of dark urine for three days. Three days before admission he had been feverish and had generalized aches and pains, profuse sweats, anorexia

Chart 4.—Levels and trends of jaundice as measured by serum icterus index determination in a mild, moderate and severe case of infectious hepatitis and in a case with relapse.

patients the average period of jaundice was prolonged over the usual to 39.8 days, with individual variations ranging from twelve to eighty days.

Recurrence.—No patients were encountered who had acquired this disease twice in the Middle East.

Postvaccinal Hepatitis.—Two patients of this series had had postvaccinal hepatitis following the administration of yellow fever vaccine one year before the onset of infectious hepatitis. Their course of disease was similar to that of the average case.

Course of Icterus.—Frequent serial determinations of the serum icterus index throughout the course of disease has demonstrated that the maximum peak of jaundice was reached within the first ten days after appearance in 80 per cent of patients. The remaining patients reached their high point during the ensuing four to five days, with the exception of a few patients

and constipation. He continued to feel bad and the day before admission had generalized abdominal pain, with nausea and vomiting.

The patient was well developed but dehydrated. He was not in acute distress. His temperature was 98.6 F., pulse rate 80 and respiratory rate 20. There was a faint icteric tint to the scleras. The heart and lungs were normal. There was generalized abdominal tenderness, and the liver was palpable 1 finger-breadth below the costal border. The leukocytes numbered 8,200, with 77 per cent polymorphonuclear leukocytes, 18 per cent lymphocytes and 5 per cent monocytes. Urinalysis showed albumin 2 plus. The serum icterus index measured 22 units. The blood Kahn reaction was negative. During the ensuing thirty days the icterus index ascended gradually to its maximum 102. During much of this time the patient was prostrated with anorexia, nausea and intermittent vomiting. Mental irritability was present and he lost approximately 12 pounds (5.4 Kg.).

Following the peak of jaundice came a slow decline of icterus over the subsequent fifty-three days. Return of appetite came slowly after the jaundice began to decline. Recovery was apparently complete and the patient was discharged after eighty-three days of hospitalization.

GROUP 4.—Relapse was a rare occurrence, being present in only 3 of 200 patients.

Case 4 represented a moderately severe case of infectious hepatitis with relapse:

CASE 4.—An enlisted man aged 24 was admitted to the hospital Nov. 7, 1943 with the chief complaints of nausea, anorexia and flatulence for eight days. His urine had been dark for five days.

The patient was well developed and nourished. His temperature was 97.4 F., pulse rate 80 and respiratory rate 20. The scleras were mildly icteric. The heart and lungs were normal, and the liver and spleen were not palpable. The leukocytes numbered 6,200, with 68 per cent polymorphonuclear cells, 28 per cent lymphocytes and 4 per cent monocytes. Urinalysis revealed bile. The serum icterus index measured 41 units, and 75 per cent bromsulphalein dye was retained in the blood after thirty minutes. The blood Kahn reaction was negative.

The icterus index reached its high point of 44 units on the eighth day of jaundice and then diminished over the ensuing week to 19 units. The patient's symptoms of anorexia and nausea had ameliorated. On the seventeenth day of jaundice, however, he began to feel worse with anorexia, nausea and discomfort in the epigastrium and right upper quadrant. The jaundice began to increase again and reached a maximum of 85 units on the twenty-sixth day of jaundice, from which point it descended over the ensuing three weeks to normal. His symptoms improved rapidly as the jaundice declined.

Nothing definite could be found which might have precipitated this relapse.

LABORATORY STUDIES

1. **Blood Counts.**—Complete blood counts were done on 183 patients at varying stages of the disease. The erythrocytes averaged 4,500,000 and the hemoglobin 85 per cent (Sahli). Total leukocyte counts were within normal limits, with rare deviations from 4,500 to 10,200 and averaging 6,200. Relatively few leukocyte counts were performed in the preicteric phase, but those done were essentially normal. A slight increase in monocytes was observed in several patients during the first ten days of the icteric phase, with individual counts as high as 14 per cent, although the average in the icteric phase was 5.2 per cent. In general there was nothing distinctive or diagnostic.

2. **Coagulation and Bleeding Time.**—The coagulation and bleeding time of the blood and erythrocyte fragility were measured in 38 and 42 patients respectively and were found to be normal.

3. **Icterus Index.**—The serum icterus index of 180 patients was measured. The reading of 10 units was

selected as the upper limit of normal, and any measurements over this were considered to be indications of icterus. Determinations at various times throughout the course of disease in 180 patients varied from 10 to 149 units. In occasional patients the serum icterus index was only slightly elevated above normal from 12 to 18 units when clinical icterus was at times impossible to detect. In many patients in whom the jaundice disappeared slowly at the end of the disease the icterus index was useful in determining whether subclinical jaundice was still present. Although the serum icterus index is less delicate than the serum bilirubin determination as a test of the excretory function of the liver, it proved a practical test under conditions in which more elaborate laboratory facilities were not available at all times.

Serum Bilirubin.—Qualitative and quantitative van den Bergh determinations were made on the serum of 60 patients, in various stages of jaundice. The qualitative van den Bergh was positive direct in all but 3 patients; many of these determinations were made within the first five days of jaundice. Two negative direct and one biphasic reaction were encountered in

Chart 5.—Correlation between height of serum icterus index and percentage of bromsulphalein dye retained in the blood thirty minutes after intravenous injection of 15.15 mg. per 55 pounds (25 Kg.) of body weight. The two determinations were made in blood drawn the same day.

patients with a serum bilirubin measuring around 1.5 mg., occurring either at the beginning or at the termination of jaundice.

The serum bilirubin determinations in this group of 60 patients ranged as high as 10.8 mg. Although a more delicate test of liver function than the icterus index determination, the inability to have available constantly the materials necessary for the performance of the test limited its usefulness under the conditions of military hospitalization.

4. **Liver Function Tests.**—As a further test of the excretory function of the liver the bromsulphalein dye retention test was used. In patients with infectious hepatitis it was found that the more pronounced jaundice the greater the amount of dye was retained in the blood, indicating the degree of severity of impairment of the function of the liver.

An effort was made to correlate the amount of bromsulphalein dye retained in the blood after thirty minutes with the height of the icterus index. Simultaneous determinations were made on 48 patients on various days ranging from the second to the thirty-second day. Patients whose icterus index was 20 or below showed little evidence of impairment of bromsulphalein dye

excretion, most of the figures ranging between 5 per cent and 15 per cent of dye retained in the blood (chart 5). As the icterus index rose, however, the retention of dye in the blood increased proportionately, so that in general the higher the icterus index the greater the amount of dye retained in the blood, up to 75 per cent dye retention. Although several patients had an icterus index ranging from 60 to 96 units, only 1 showed more than 75 per cent retention of bromsulphalein in the blood.

5. *Blood Kahn Reaction.*—Kahn tests were performed on 180 patients in various stages of the disease in both preicteric and icteric phases. One patient had a 2 plus reaction on the sixteenth and twenty-fifth days of disease. No history of venereal exposure was elicited and it was thought that the positive reaction was related to the acute infection. Subsequent tests were advised, but we were unable to follow the patient.

6. *Urinalysis.*—Of 184 patients on whom urinalysis was performed 72 (39 per cent) had albumin early in the course of disease, frequently in the preicteric phase. Increased urobilinogen in the urine was found to be a good diagnostic measure before clinical jaundice was evident. Biliuria was most often the first evidence of jaundice presented by the patient, and it persisted throughout the greater part of the icteric phase. Otherwise the urine was normal.

7. *Stools.*—In a large number of cases the stool became light in color early in the icteric phase, and in the more severely sick patients acholic stools were common, although exact percentages were not obtained. This was frequently associated with constipation and flatulence.

Cultures were made of the stools of 58 patients, and of those 12 per cent were found to contain dysentery bacilli of the Flexner or Hiss group. This percentage of carriers was not unusual for troops in the area at this time. Diarrhea was usually not associated with the positive stools and, since most of the patients had had previous history of diarrhea, it was assumed that they were carriers. They were treated with sulfaguanidine in therapeutic doses.

THERAPY

The treatment of this disease was symptomatic. It was entirely possible for those patients with subclinical jaundice or very mild disease to remain ambulatory, but for the sicker patients hospitalization with bed rest was indicated during the acute phase, since activity apparently aggravated the symptoms of even the mildly sick when they were obliged to live under field conditions. As recovery took place and jaundice waned, increasing activity according to the tolerance of the individual patient was advised. Chilling and excessive activity were avoided.

Full, unrestricted diet was given as soon as the patient could tolerate it. Supplementary vitamins were added, although their utilization and value were undetermined. Early in the course of disease when anorexia, nausea and upper abdominal discomfort were present, difficulty was encountered in providing adequate food intake. Diet rich in proteins and carbohydrate was given. No advantage was demonstrated for excessive intake of carbohydrates except that it provided for some patients a more palatable way of increasing their amount of food eaten. Fats were not withheld unless the patient was unable to tolerate them. This occurred at times when bile was completely absent from the

gastrointestinal tract. Frequent small feedings were better tolerated than large meals at longer intervals.

Duodenal drainage was performed on 90 of the 200 patients as a "therapeutic" measure. The average duration of jaundice in all patients was twenty-seven days. In the 110 patients who did not have biliary drainage the average period of jaundice was 23.8 days, while in the 90 patients who had biliary drainage performed the average period of jaundice was thirty-one days. No reason could be found to account for this discrepancy. There was no selection of cases according to severity. Sixty per cent of the drainages were done within the first ten days of jaundice when most of the patients were reaching their maximum icterus. It is of interest to note that in most cases in which drainage was performed during the height of jaundice no B (dark) bile was obtained. It is impossible to draw any inference from these data to indicate that biliary drainage had any beneficial effect. No opinion can be given as to whether it had any effect on prolonging the jaundice.

Constipation was relieved by the administration of $\frac{1}{2}$ to 1 ounce (15 to 30 Gm.) of crystalline sodium sulfate in warm water each morning before breakfast. Many patients stated that this afforded relief of the sense of fullness and epigastric oppression.

Anorexia, nausea and vomiting were ameliorated at times by giving 0.0325 Gm. of phenobarbital three times daily, but intractable vomiting at times required the administration of parenteral fluids in the form of 2,000 to 3,000 cc. of 5 per cent dextrose in isotonic solution of sodium chloride intravenously.

Upper abdominal distress was severe enough at times to require codeine sulfate 0.065 Gm., but frequently the application of local heat was of benefit.

Itching was relieved by the administration of 0.0325 Gm. of phenobarbital three times daily, and for more severe cases the local application of calamine lotion containing 1 per cent phenol afforded relief.

Sulfonamides.—Seven patients in this group of 200 patients received sulfonamides in full therapeutic dosages. Six of them had sulfaguanidine for dysentery and 1 sulfathiazole for chancroid. To all patients the drug was given early in the course of jaundice. One patient had a relapse of jaundice about four weeks after the cessation of sulfaguanidine. However, the course of jaundice in this group of seven averaged twenty-three days, with individual variations ranging from twelve to forty-six days, so that no evidence was available from this small number that sulfonamides were detrimental.

SUMMARY

Infectious hepatitis has assumed epidemic proportions in British, Italian, German, French and American troops during the past two to three years in the Middle East, with a sharp seasonal prevalence beginning in late October and reaching a peak in late January.

The clinical picture of the disease among 200 American troops admitted to an American General Hospital in the Middle East was found to be similar to that described by British observers.

An acute onset initiated a clearly defined preicteric period of five days characterized by anorexia, chilliness, fever, headache, nausea, vomiting, upper abdominal discomfort and generalized aches and pains.

This phase was terminated by the decline of fever and the appearance of dark urine, which marked the onset of the icteric phase. Anorexia, nausea, vomiting and epigastric distress were associated with hepatic

enlargement and tenderness during the first ten days of jaundice; at the end of this period the icterus usually diminished and the signs and symptoms regressed. Recovery was uneventful in practically every case. Only 3 patients had relapse, and no associated etiologic factor could be determined in these cases. The average duration of jaundice was twenty-seven days, and patients over 30 years of age averaged five days more in duration of icterus. Patients who received anti-syphilitic therapy within three months before the onset of disease had their jaundice prolonged twelve days more than the average. A few patients received sulfonamide, and no effect could be observed on the jaundice.

Individual patients manifested all degrees of severity of disease, ranging from the mild case with subclinical jaundice in which icterus was detected only by examination of the urine and blood serum to the severely prostrated patient with deep jaundice prolonged over a period of eighty-three days. Eighty-one per cent of patients had mild to moderately severe disease, while 19 per cent had severe jaundice.

Laboratory studies revealed that blood counts, coagulation and bleeding time and erythrocyte fragility tests were normal. The serum icterus index was used as a measurement of icterus and was found to be valuable both alone and in conjunction with the bromsulphalein dye retention test. It was found that the percentage of dye retained in the blood was in direct proportion to the height of the icterus index. The blood Kahn tests were negative in all but 1 patient.

Urinalysis gave the most important early clue to diagnosis, and the occurrence of biliuria cannot be stressed enough as an important diagnostic measure. Albuminuria was present in a goodly percentage of patients.

Duodenal drainage was performed on a large number of patients early in the course of jaundice and failed to shorten the disease.

Pigment disappeared from the stools of a large number of the patients as the icterus approached its height and, in the severely sick, acholic stools were common.

CONCLUSIONS

1. Data from 200 cases of infectious hepatitis in American troops occurring between Nov. 11, 1942 and Feb. 1, 1944 in the Middle East were assembled and analyzed.

2. The course of disease in these troops simulated the clinical descriptions of British observers.

3. Because of prolonged hospitalization (average 28.8 days) infectious hepatitis constitutes a problem of military importance.

4. The most important simple laboratory procedure in diagnosis was examination of the urine for bile at the bedside of the patient by the medical officer.

5. The serum icterus index determination afforded a simple, effective method of following the course of jaundice and demonstrating subclinical icterus under the circumstances of military hospitalization.

Fuel Requirement of Man.—The energy requirement of a person for twenty-four hours or for a shorter period, expressed in calories, can be determined with a high degree of accuracy. This figure is the sum of (a) the basal metabolism, (b) the energy liberated in exercise or work and (c) the increment of energy due to the specific dynamic action of food, the so-called cost of digestion.—McLester, James S.: *Nutrition and Diet in Health and Disease*, Philadelphia, W. B. Saunders Company, 1943.

EFFECT OF INTRAVENOUS FLUIDS ON DEHYDRATED PATIENTS AND ON NORMAL SUBJECTS

CARDIAC OUTPUT, STROKE VOLUME, PULSE RATE AND BLOOD PRESSURE

JAMES D. HARDY, M.D.

AND

LINCOLN GODFREY JR., M.D.

PHILADELPHIA

Dehydration is frequently encountered in both medical and surgical patients. Whether dehydration is the result of vomiting, diarrhea, inability to swallow or electrolyte derangement such as occurs in diabetic acidosis,¹ the intravenous administration of fluids is the mode of therapy usually relied on to restore the normal state of hydration and electrolyte balance. Indeed, so routinely and with such gratifying results are intravenous fluids used for these patients that the physician seldom pauses to consider the exact effect of his therapy

Fig. 1.—The cardiac output of the normal subjects has been averaged and is compared graphically with the average of the dehydrated patients, before and after intravenous fluid administration.

on the cardiovascular system. Previous reports in the literature have dealt with the effect of intravenous infusions on pulse rate, blood pressure, blood volume, venous pressure, velocity of blood flow and the electrocardiogram.² Altschule and Gilligan³ have also reported the changes in cardiac output in normal men. However, no workers, so far as we are aware, have studied the effect of intravenous fluids on cardiac output in dehydrated patients as compared with the effect on normal subjects. For this reason, two such groups have been investigated and the results are reported here. Except in 1 instance, in which no blood chemistry determinations were done, no patient was considered

dehydrated who did not present abnormal blood chemistry values as outlined in the table. The dehydrated individuals experienced a pronounced increase in cardiac output after the infusions, while the normal subjects presented little or no such rise.

CLINICAL MATERIAL

The patients were examined as soon as possible after reaching the hospital, and when dehydration was found to exist the subject was taken on a litter directly to the ballistocardiograph, having no treatment prior to the test. Blood was drawn for determinations of serum protein, serum chloride and blood urea nitrogen. The diagnoses of the dehydrated subjects are listed in the table. The control group consisted of the authors, of subject J. M., tested first just after admission when he was dehydrated, who volunteered to repeat the test

Fig. 2.—Typical ballistocardiographic tracings of a normal subject before and after intravenous fluid administration are compared with those of a dehydrated patient. Top subject, L. G. before fluids. Second, L. G. after 3,000 cc. of intravenous fluid. Third patient, J. M. before fluids. Fourth patient, J. M. after 3,000 cc. of intravenous fluid. The time record applies to all tracings. Largest interval equals one second.

fifteen days later when all evidence of dehydration had disappeared, and of 3 patients normal from the point of view of this study but to whom it was necessary to give fluid intravenously. The blood chemistry values for this group are recorded in the table; all were within the normal range.

TECHNIC

The intravenous fluids were given with the subject lying on the ballistocardiograph table,⁴ so that measurements of cardiac output could be made at will. The ballistocardiograph consists essentially of a table suspended by wires and free to move in a lengthwise direction only, of an optical system attached to the

table which magnifies its movements by the deflections of a beam of light, and of a camera which photographs the movements of the beam of light. When the patient lies lengthwise on the table, the recoil of his body downward when ejection of blood from the heart commences, followed by a movement upward when the blood is turned by the aortic arch, is transmitted to the ballistocardiograph table and a corresponding deflection of the beam of light is produced. In persons of the same age, height and weight the greater the excursions of the beam of light, the greater is the stroke volume. Cardiac output was calculated by the area method and the correction of Cournand, Ranges and Riley⁵ was employed. By means of a timer, the heart rate can be calculated from the film.

After the subject had lain quietly on the table for fifteen minutes, readings of cardiac output, stroke volume, pulse rate and blood pressure were taken. Following this, intravenous fluids were begun at a rate of around 20 cc. per minute, approximately two hours being required for the administration of 2,500 cc. Though there was an occasional exception, the first liter of fluid was usually isotonic solution of sodium chloride, the second 5 per cent dextrose in isotonic solution of sodium chloride and the third (when used) 5 per cent dextrose in water. Ballistocardiograms, pulse rate and blood pressure readings were taken after each liter of fluid. Owing to the illness of the dehydrated patients, the observations were terminated as soon as all the necessary fluid was in.

RESULTS

From the data recorded in the table, it will be seen that the cardiac output of the dehydrated group, expressed as percentage deviation above or below the average normal cardiac output per pound per minute,⁶ increased substantially with the administration of intravenous fluids, while that of the normal group underwent no such rise. These results are represented graphically in figure 1. The increases in cardiac output were caused chiefly by increases in stroke volume. In figure 2 are typical ballistocardiograph tracings of a normal subject and of a dehydrated patient, taken before and after the intravenous administration of fluids.

Of particular interest were the responses of 1 patient (J. M.). He was admitted to the hospital acutely dehydrated with symptoms suggestive of pyloric obstruction due to a peptic ulcer. After the administration of 3,000 cc. of fluid intravenously, his cardiac output rose 41 per cent. He responded well to conservative therapy and was eating a normal diet within one week. Fifteen days after admission he was again given 3,000 cc. of fluid, and this time his cardiac output fell 1 per cent.

It is worth noting that 3,000 cc. of fluid administered intravenously provoked no subjective symptoms in any of the normal subjects, but it was followed by a prompt diuresis.

COMMENT

It was evident that the normal persons had to void frequently during the infusion and that the dehydrated patients did not. Thus in the latter group more fluid was retained in the body. Previous workers⁷ have

shown that fluids given intravenously usually increase the circulating blood volume, and this doubtless occurred in most of our dehydrated patients. But in 1 dehydrated subject no dilution of blood proteins was demonstrated after the infusion. Though it is possible that a change in serum protein within the limits of laboratory error occurred, the increased cardiac output in such a case might be attributed partly to an improved condition of the myocardium, and of the vasomotor center of the brain when needed sodium chloride and water were supplied. That intravenous dextrose can

the feeling of general well-being so often experienced by the dehydrated patient after receiving fluid intravenously is accompanied by concomitant objective changes in the circulatory dynamics. That the maximum effect is quite often produced by the first liter of fluid suggests that this amount may be sufficient in instances in which there is danger of giving too much fluid intravenously. To state this somewhat differently, when giving fluids intravenously to dehydrated patients one should remain aware of the increased work which such therapy imposes on the hearts of these persons.

stimulate a diseased heart was demonstrated by Edmunds and Cooper,⁸ but in our experiments the maximum increase occurred after the first liter of fluid before any dextrose had been given; so we are not inclined to weigh this factor heavily. Despite the uncertainty regarding the exact mechanism, it is obvious that intravenous fluids may cause effects in diseased subjects very different from those observed in healthy persons.

In conclusion, several clinical considerations merit emphasis. It is evident from the results recorded that

SUMMARY

1. The effect of intravenous fluids on the cardiac output, stroke volume, pulse rate and blood pressure of a group of dehydrated patients was compared with similar observations made in a group of subjects not demonstrably dehydrated.

2. The dehydrated group manifested a prompt and significant rise in cardiac output, resulting chiefly from an increase in stroke volume, and this was accompanied by a small increase in the pulse pressure.

3. Similar effects were not observed in the control group, although a smaller and more delayed increase in cardiac output was found in 2 subjects who had been vomiting.

Clinical Notes, Suggestions and New Instruments

COMPRESSION OF SEVENTH CERVICAL NERVE ROOT BY HERNIATION OF AN INTERVERTEBRAL DISK

PAUL C. BUCY, M.D., AND HARVEY CHENAULT, M.D.
CHICAGO

Several cases of herniation of a cervical intervertebral disk have been recorded in the literature, but nearly all of these have been instances in which compression of the spinal cord itself by a midline herniation predominated.¹ Semmes and Murphy² mention 4 cases from the literature which presented symptoms of compression of a cervical nerve root without involvement of the spinal cord and present 4 similar cases of their own. Three of the latter cases of unilateral herniation of a cervical intervertebral disk were verified by operation. The syndrome of compression of the seventh cervical nerve root as shown in the latter 4 cases was remarkably constant and occurred on the left side in all 4. All these patients gave a history of numerous "cricks" in the neck for months or years preceding the severe attack. Two gave a definite history of trauma to, or motion of, the neck as precipitating factors. In all the predominant symptom was excruciating pain. The radiation of the pain was to three regions: "(1) the precordium, (2) a point just medial to the upper angle of the scapula and (3) down the lateral and medial surfaces of the arm." In the 3 cases which presented objective sensory loss the disturbance consisted of hypalgesia and hypesthesia "limited to the index and middle fingers without involvement of the thumb, the hand or the forearm."

Recently there has come under our observation such a case of unilateral herniation of a cervical intervertebral disk in which there were certain differences from the syndrome as presented by Semmes and Murphy.

REPORT OF CASE

C. H., a white man aged 41, a factory fireman, referred by Dr. Luther J. Osgood of Waukegan, Ill., was admitted to the Illinois Neuropsychiatric Institute on Dec. 1, 1943 with a complaint of "pins and needles," "creeping" or "electricity" in the thumb, index and middle fingers of the right hand, which extended up the radial aspect of the right forearm. The past medical, family and marital histories were irrelevant.

The patient stated that he was quite well until January 1938, when he slipped and fell in an icy alley, striking the back of his head and shoulders on the pavement. He was not knocked unconscious and continued on his way to work with only a

mild headache, which lasted not longer than two hours. He thereafter felt well and had no pain in the neck or shoulders from the fall. He did not even develop any swelling of his scalp. However, two days later he began to have a dull, continuous, aching pain in the region of the right shoulder blade (he indicated a localized area just beneath the medial portion of the spine of the scapula). The pain became increasingly severe in the next week. As a result he had to leave his work as a fireman.

The pain remained localized, nonradiating and severe. There was no associated numbness or paresthesias comparable to the present complaint at that time. He had chiropractic treatments, which made the pain so much more severe that he was obliged to stop them. Conservative treatment with heat and medicines prescribed by numerous physicians was to no avail. The pain in the region of the scapula gradually disappeared after six or seven weeks. Thereafter he was quite well in all respects and able to continue his work until six months later (summer of 1938), when he had another bout of the same pain, lasting three weeks. This time the scapular pain was associated with a sensation of "pins and needles" in the right thumb and the index and middle fingers, which extended up the radial aspect of the forearm nearly to the elbow. Osteopathic treatments were given, and again both the pain and the paresthesias gradually receded. Thereafter he was entirely

Area of hypesthesia resulting from compression of the right seventh cervical spinal root by a herniation of the intervertebral disk.

well for one and a half to two years, when in 1940, without a known precipitating cause, he had a very severe recurrence of the same pain in the same location which lasted altogether about six months. The pain was again associated with the same paresthesias and was excruciating. It was so aggravated by lying down that for two months he had to sleep sitting upright in an easy chair. He went to numerous physicians, one of whom operated on the right side of his neck (apparently an anterior scalenotomy) without relief. The pain and paresthesia gradually receded over the next three months, during which time he received physical therapy to the right upper extremity for approximately two months.

He was again entirely well until about June 1943 (six months prior to admission), when he noticed recurrence of the paresthesias without pain the day after helping a friend move his household belongings. The abnormal sensations were continuous up to his admission here, but at no time after 1940 did he experience a recurrence of the pain from which he suffered earlier. If he held himself perfectly still, he experienced none of the paresthesias. He usually slept with his right hand underneath his head. Raising either arm above his head, throwing his head back in hyperextension of the neck, or moving the neck about in nearly any way evoked the crawling sensation in the right thumb and the index and middle fingers, extending up the radial border of the right forearm. Specific questioning revealed no history of "cricks" in the neck before or during the present illness. Though he had no pain, the paresthesias

2. Semmes, R. E., and Murphy, F.: The Syndrome of Unilateral Rupture of the Sixth Cervical Intervertebral Disk with Compression of the Seventh Cervical Nerve Root, J. A. M. A. 121: 1209-1214 (April 10) 1943.

were of such severity that the patient desired operation for relief.

The general physical examination revealed nothing significant. The patient was quite husky and robust. There were the scars of an appendectomy and of the scalenotomy. Neurologic examination disclosed that he was tense and anxious. However, he was well aware of his "nervousness" and was quite reliable and consistent in his statements. There was no tenderness of the spine at any point, but hyperextension of the neck invariably initiated the paresthesias in the right forearm. The Naefziger test, using the blood pressure cuff about the neck, also produced the same result. When walking or standing, the patient held the right hand supported in his shirt-front in the Napoleonic attitude and said that doing so relieved the paresthesias.

The patient was quite strong and muscular and was right handed. Accordingly, a mild weakness of extension of the right triceps muscle as compared to the left was felt to be significant, though there was no perceptible difference in the triceps reflexes. There was no demonstrable motor weakness of the hand or wrist. The sensory examination showed an area of hypalgesia, hypesthesia and hypothermesthesia over the right thumb and the index and middle fingers and on the radial border of the forearm, as shown in the illustration. Deep sensibility in this area was intact to the usual clinical tests. There was no area of complete analgesia except possibly on the tip of the index finger, but the skin of his hand was thick and horny, and for this reason absolute certainty could not be attained. The remainder of the entire neurologic examination showed normal findings. Laboratory examinations of the blood and urine were all negative, and x-ray films of the cervical spine showed no pathologic changes. On lumbar puncture the initial pressure of the spinal fluid and the alterations produced by compression of the jugular veins were entirely normal. The fluid was clear and colorless. It contained no excess of cells and only 12 mg. of protein per hundred cubic centimeters.

A diagnosis of herniation of the fifth cervical intervertebral disk compressing the right seventh cervical nerve root was made. This region was explored on Dec. 7, 1943 under general anesthesia. The spines and right laminae of the sixth and seventh cervical vertebrae were exposed. A small amount of the inferior part of the sixth and the superior part of the seventh laminae and the ligamentum flavum were removed, exposing the seventh cervical nerve root. It was quite fixed at its exit through the intervertebral foramen by an obvious small protrusion directly anterior to it. When the nerve root was retracted upward there was visible a small herniation. It had the characteristic glistening white dome and felt rubbery. Incision of the posterior spinal ligament over this protrusion resulted in the spontaneous extrusion of the entire piece of herniated cartilage. It measured not over 3 by 3 mm. in diameter. No further loose material was found, and there was no opening into the disk of sufficient size to warrant further search into it. Removal of the small mass left the nerve root quite free and mobile, and the wound was closed.

The postoperative course was uneventful and the patient was almost entirely relieved of his symptoms. None could be induced by any posture, and as soon as testing could be made there was no demonstrable hypalgesia except on the tips of the index finger and the thumb. Even this objective hypalgesia had receded when he left the hospital on the sixteenth postoperative day, and only a sensation of subjective numbness in the tip of the index finger persisted.

SUMMARY

A man aged 41 developed herniation of the intervertebral disk between the sixth and seventh cervical vertebrae on the right side as the result of a fall on an icy street. This gave rise to repeated attacks of severe pain just below the medial part of the spine of the right scapula and persistent paresthesias of the thumb and the index and middle fingers and the radial border of the forearm, all on the right side. Removal of this small piece of herniated cartilaginous material through a partial hemilaminectomy gave immediate complete relief from all symptoms.

3. To eliminate confusion, it would probably be best to speak of the intervertebral disk between the sixth and seventh cervical vertebrae, but since there is no intervertebral disk between the first and second cervical vertebrae it is actually the fifth cervical disk whose extrusion compresses the seventh cervical nerve root at its exit.

FRACTURE OF THE BASE OF THE THUMB

A NEW METHOD OF FIXATION

ERIC C. JOHNSON, M.D., SAVANNAH, GA.
Surgeon, U. S. Public Health Service

Waugh and Ferrazzano¹ and Berkman and Miles² recently reported a new method of treatment of fractures of the metacarpals, exclusive of the thumb. This method consists in reducing the fracture, pushing a Kirschner wire through the fragment and then running the wire on through into the adjacent metacarpal, thus fixing the loose fragment. There is no reason why this same principle cannot be used for metacarpal fractures of the thumb, particularly the Bennett type of fracture involving the base of the thumb.

Fig. 1 (case 1).—Fracture of base of thumb.

Fig. 2 (case 1).—Complete reduction with Kirschner wire fixation and cast.

As textbooks and medical journals as far as is known have not described this technic, it is considered worth recording.

Fractures involving the base of the thumb usually give sufficient deformity, discomfort and loss of mobility to warrant the use of a method that will result in a complete anatomic reduction. If the hand is anesthetized and the assistant pulls on the thumb, the fracture can be reduced but the question is how to maintain this reduction. While the assistant is pulling on the thumb in such a manner that the first metacarpal is lined up on the same plane as the second metacarpal, the operator may then introduce a Kirschner wire into the radial side of the metacarpal shaft, just volar to the extensor tendons.

1. Waugh, R. L., and Ferrazzano, G. P.: Fractures of the Metacarpal Exclusive of the Thumb, *Am. J. Surg.* 59: 186 (Feb.) 1943.

2. Berkman, E. F., and Miles, G. H.: Internal Fixation of Metacarpal Fractures Exclusive of the Thumb, *J. Bone & Joint Surg.* 25: 816 (Oct.) 1943.

After the wire has been passed through the shaft and through the first interspace, it is run through the second metacarpal shaft. A small plaster cast can then be applied to the hand and wrist while the assistant is still holding the thumb. The fixation by the Kirschner wire and the plaster cast will maintain

Fig. 3 (case 1).—Result: no deformity, fracture line imperceptible after six weeks.

the reduction. If the operator is not certain that one wire has done the trick, he can insert another wire beside the first one and get a firmer fixation with the two wires.

CASE 1.—On June 11, 1943 R. W., a girl aged 19 years, "grease monkey" at an army air base, was filling a tire when the tire blew up. She sustained a fracture of the base of the first metacarpal of the left hand and a fracture through the head of the third metacarpal and the base of the fourth metacarpal of the right hand. With the patient under general anesthesia a Kirschner wire was passed through the distal end of the second metacarpal and through the fractured head of the third metacarpal of the right hand, and a small cast was applied. The problem of how to treat the Bennett's fracture of the thumb of the left hand was then considered. Since fixation of fragments by the use of Kirschner wire had obtained good results in fractures of the other metacarpals, it was decided to try this method in a fracture of the first metacarpal. The thumb was grasped firmly and pulled out

Fig. 4 (case 2).—Comminuted fracture of base of thumb involving joint surface.

and back so as to bring the first metacarpal shaft on the same plane with the second metacarpal shaft. The assistant pressed forward on the back of the second metacarpal and backward on the front of the first metacarpal. A Kirschner wire was then pushed through the midshaft of the first metacarpal and on through the shaft of the second metacarpal. A light cast

was applied. X-ray examination showed that a complete anatomic reduction had been obtained. Within six weeks the fracture was completely healed and the patient had full range of motion, with no deformity.

CASE 2.—On July 3, 1943 J. B., a seaman aged 30 was admitted with a fracture at the base of the first metacarpal of the right hand, following a fist fight. The same method of treatment was used. In this case, since it was not sure that the Kirschner wire had properly impaled the second metacarpal, another wire was inserted and the cast applied. X-ray examination showed that both wires were in good position and that there was an excellent anatomic reduction. Within eight weeks the fracture line was no longer visible and the joints of the thumb were freely mobile and painless.

Fig. 5 (case 2).—Complete reduction by traction; fixation by two pins.

Fig. 6 (case 2).—Result after eight weeks: normal bone and joint contour; fracture line imperceptible

SUMMARY

A simple method for an anatomic reduction of fractures of the base of the first metacarpal has been employed. The convalescence and results of the method have been highly satisfactory both to the patient and to the surgeon.

U. S. Marine Hospital.

Medical Point of View of Criminals.—From the medical point of view, criminals can be classified broadly under the headings of normal, subnormal, mentally defective, psychoneurotic, psychopathic and psychotic. But the groups sometimes overlap, and no psychiatric classification is likely to give entire satisfaction until the dividing line between mental diseases and character anomalies is established with some degree of precision apart from personal estimates.—East, W. Norwood: *The State, the Criminal and the Psychiatrist*, *Proc. Roy. Soc. Med.* 37:11 (Nov.) 1943.

COUNCIL ON PHARMACY AND CHEMISTRY

At periodic intervals the Council on Pharmacy and Chemistry will offer brief statements on the present status of therapeutic or prophylactic procedure in fields of current interest. This information will be selected for its special value to those engaged in general practice.

Austin E. Smith, M.D., Secretary

COMPARATIVE COST OF VITAMIN MIXTURES

The multiplicity of mixed vitamin preparations that are now available in commerce has created much confusion. According to the promotion claims, each preparation is supposed to be

Daily Vitamin Requirements

Vitamin	National Research Council Recommended Daily Allowances †	Food and Drug Administration Recognized Minimum Daily Requirements
A.....	5,000 units	4,000 units
D.....	† units	400 units
B ₁ (thiamine hydrochloride)...	2 mg.	1 mg.
B ₂ (riboflavin).....	3 mg.	2 mg.
Niacin amide (nicotinic acid)...	20 mg.	•
C (ascorbic acid).....	75 mg.	30 mg.

* The minimum daily requirement of nicotinic acid has not been established, but there appears to be fairly good agreement among those qualified to speak authoritatively on the subject that 10 mg. is approximately the minimum daily requirement for this vitamin.

† Applicable to 3,000 calories intake for adult.

‡ 400 to 800 units of vitamin D recommended for pregnancy, lactation and children under one year.

better than all others. Sometimes the claims are based on some unique manufacturing technic, sometimes on the addition of minerals and often on the addition of vitamins other than those

for which minimum daily requirements have been set. For recognized claims relating to vitamin therapy the physician should consult New and Nonofficial Remedies.

During June 1944 a survey was made of multiple vitamin products offered in one of the largest department stores in the United States. The selling costs and declared contents are tabulated herewith. For purposes of comparison the price rate per hundred capsules or tablets has been based on the package nearest to 100 that is manufactured by the firms. For example, if a manufacturer provides only 50 tablet packages for one dollar, 100 of the tablets are estimated to cost two dollars. Obviously, if any firms who do not now make a package of 100 should decide to do so subsequently, such cost figures may be different—probably lower.

None of the following preparations stand accepted by the Council for inclusion in New and Nonofficial Remedies. Further, the advertising claims offered on behalf of some of the mixtures preclude any possibility of their acceptance. The accompanying table is offered solely to emphasize the importance of examining the labels and of using standard reference sources such as New and Nonofficial Remedies to ascertain recognized actions and uses and to compare these with the profuse and deceptive statements prepared by the more ebullient promoters.

SATURDAY, SEPTEMBER 2, 1944

INDUSTRIAL HEALTH SERVICE FOR FEDERAL EMPLOYEES

Recently hearings were conducted in Washington on H. R. 4909 by the subcommittee of the House Committee on Civil Service. This bill proposes to make available to federal government employees the kind of medical service found generally advantageous to private industry. Dr. Carl Peterson, Secretary of the Council on Industrial Health of the American Medical Association, presented the views of the Council on the essential elements of a good industrial health service:

1. A competent physician who takes genuine interest in applying the principles of preventive medicine and hygiene to employed groups and who is willing to devote regular hours to such service in the working environment.

2. Industrial nurses with proper preparation, acting under the physician's immediate supervision or under standing orders developed by him or by the committee on industrial health of the county medical society.

3. Industrial hygiene service directed at improvement of working environment and control of all unhealthful exposures, to be provided by physicians and others with guidance and assistance from the specialized personnel in state and local bureaus of industrial hygiene.

4. A health program, which should include:

- (a) Prompt and dependable first aid, emergency and subsequent medical and surgical care for all industrially induced disability.

- (b) Health conservation of employees through preventive medicine, physical supervision and health education.

- (c) Close correlation with family physicians and other community health agencies for early and proper management of nonoccupational sickness and injury.

- (d) Good records of all causes of absence from work as a guide to the establishment of preventive measures.

5. Adequate compensation for industrial health personnel.

In respect to treatment, the Council on Industrial Health draws two clear distinctions:

1. Treatment of compensable injuries and diseases: The disabled worker should be free to choose his physician from all those licensed doctors of medicine competent to supply the required services except in situations provided for by chapter III, article VI, section 3 of the Principles of Medical Ethics, which reads as follows:

The phrase "free choice of physician," as applied to contract practice, is defined to mean that degree of freedom in choosing a physician which can be exercised under usual conditions of employment between patient and physician when no third party has a valid interest or intervenes. The interjection of a third party who has a valid interest or who intervenes does not per se cause a contract to be unethical. A "valid interest" is one where, by law or necessity, a third party is legally responsible either for the cost of care or for indemnity. "Intervention" is the voluntary assumption of partial or full financial responsibility for medical care. Intervention shall not proscribe endeavor by component or constituent medical societies to maintain high quality of service rendered by members serving under approved sickness service agreements between such societies and governmental boards or bureaus and approved by the respective societies.

2. Treatment of noncompensable injuries and diseases: The treatment of injuries or diseases not industrially induced is the function of private medical practice. The physician in his industrial relationships should abstain from such services except in the case of:

- A. Minor ailments. The physician in industry may treat minor physical disorders which temporarily interfere with an employee's comfort or ability to complete a shift, and for the relief of which he may need immediate medical attention.

- B. First aid for urgent sickness. The physician in industry should employ such measures as the emergency dictates in all cases of urgent sickness occurring during working hours on the working premises, until such time as prompt notification of the family physician relieves him of further responsibility.

- C. Rehabilitation after sickness and injury. The physician in industry can properly assume responsibility for those phases of rehabilitation after disability industrially induced or otherwise which progress best under controlled working conditions.

Examination of the bill indicated that its proposals did not diverge greatly from the Council's position. During the hearings the committee seemed to be genuinely concerned about the values to be received from such expenditure of public funds, specifically reduction of lost time from sickness, improved production and improved personnel relations. Representatives of man-

agement, labor and medicine who testified were all in general accord that these benefits commonly observed in industry should prevail with equal force in the government. There was objection to the proposal that these industrial health services be set up only on recommendation of the Civil Service Commission after consultation with the United States Public Health Service. The alternative recommendation was that each agency be responsible for its own health program but that each agency may secure medical services by agreement with the Public Health Service. The committee particularly asked for reassurance that a health program of this kind would supplement rather than supplant the activities of the private physician. The general tone of the hearings lent encouragement to the hope that a health service could be organized for government workers along lines which experience in private industry has proved dependable and successful.

THE MODE OF ACTION OF THE SULFONAMIDES

During the course of the development of sulfonamide chemotherapy many theories have been propounded relative to the fundamental mode of action of these agents. A recent review by Henry¹ discusses certain of the existing theories. Early belief that the sulfonamides stimulate the defensive powers of the host or inactivate bacterial toxins are, in light of present knowledge, rather questionable. The primary action of these drugs is now generally agreed to be on the bacteria themselves, and the important manifestation of this action is bacteriostasis. How then do the sulfonamides act on bacteria to inhibit their growth?

The assumption that the sulfonamides are oxidized in the body to their hydroxy derivatives led to the so-called anticatalase theory of their mode of action. This theory assumed that bacteria convert sulfonamides to hydroxy derivatives, which inhibit the enzyme catalase. The absence of this enzyme was supposed to allow the hydrogen peroxide from bacterial metabolism to accumulate to a point at which it inhibited bacterial growth. This theory was discredited by the subsequent observations that certain bacteria are inhibited by sulfonamides (*a*) in the absence of catalase (*b*) even though they do not produce peroxide (*c*) although they are peroxide resistant and (*d*) in the absence of conditions necessary for the production of peroxide (i. e. anaerobic organisms).

As a result of the now extensively confirmed observation that para-aminobenzoic acid inhibits the sulfonamide effect, a currently popular theory of the mode of action of the sulfonamides developed. This theory is based on the assumption that para-aminobenzoic acid is an essential metabolite for bacterial growth, participat-

ing in the formation of certain vital enzyme systems. It was claimed that the sulfonamides, because of close chemical similarity to para-aminobenzoic acid, were capable of forming ineffective substitutes for this essential metabolite in vital enzyme systems. This theory has done much to further our knowledge of the pharmacology of the sulfonamides. However, the failure of this theory to explain certain recent observations has led to a rather critical reexamination of its claims. If the para-aminobenzoic acid theory is valid, then the widespread effectiveness of the sulfonamides as cell inhibitors would indicate that para-aminobenzoic acid is an almost universally essential metabolite. This, however, remains to be shown positively. According to Henry, para-aminobenzoic acid has been demonstrated to be an essential metabolite for only one of the pathogenic bacteria, the diphtheria bacillus. A number of other inhibitors of the sulfonamides, such as certain purines, amino acids, glucose, mercuric chloride and urethane, have now been demonstrated. If the logic of the para-aminobenzoic acid theory is established, these substances should also be considered essential metabolites, a view that is obviously fallacious with regard to certain of these inhibitors.

Finally, it was observed in a charcoal model that para-aminobenzoic acid can competitively inhibit the action of the sulfonamides without in itself being an "essential metabolite." Sulfanilamide inhibits the adsorption of methylene blue by charcoal and is in turn inhibited in this respect by para-aminobenzoic acid. Para-aminobenzoic acid therefore effectively antagonizes most of the actions of the sulfonamides, with the exception of certain toxic actions in mammals. The method of this antagonism is not well understood, and its direct relationship to the mode of action of the sulfonamides is somewhat questionable. The sulfonamides inhibit various of the known respiratory enzyme systems. The inhibition of bacterial multiplication bears a direct relationship to the inhibition of respiratory mechanisms of these bacteria, either aerobic or anaerobic.

A recent theory of the mode of action of the sulfonamides postulates that their chemical similarity to the whole or part of various coenzyme molecules allows them to combine with the specific proteins of the respiratory enzymes with either the displacement of the coenzyme by the drug or the formation of an inactive "drug-protein-coenzyme" complex.

A substantial fraction of the overall oxygen consumption of the cell still remains when cell division is completely stopped by the sulfonamides. Henry has therefore suggested that the action of the sulfonamides on bacteria resembles the action of certain narcotics, especially in regard to the more or less specific inhibition of that relatively small portion of the total respiration concerned with supplying the energy for cell division.

1. Henry, Richard J.: The Mode of Action of the Sulfonamides, *Bact. Rev.* 7: 175, 1943.

The specific cellular respiratory enzyme systems against which the sulfonamides act have not as yet been clearly identified, nor has the manner in which these systems are altered been portrayed.

CHEMOSURGICAL TREATMENT OF CANCER OF THE LIP

The chemosurgical method was introduced by Mohs¹ for the excision of accessible forms of cancer under microscopic control. The tissues in question are fixed in situ by means of a suitable solution of zinc chloride and then excised and examined microscopically. This process is repeated if necessary until microscopically cancer free surfaces are reached. The fixation of the tissue by the zinc chloride does not interfere with the microscopic work. A special clinic was established in the department of surgery in the University of Wisconsin eight years ago, and since then many hundreds of cases of cancer have been subjected to the chemosurgical treatment. The results are now becoming available for analysis and evaluation. The first report on these results deals with cancer of the lip.²

The report covers the cases treated between July 7, 1936 and May 29, 1943. The cure rates are 91.5 per cent of 164 cases after six months, 59 per cent of 73 cases after three years and 87.5 per cent of 38 cases after five years. The cure rate of 87.5 per cent after five years appears to surpass recently published rates for surgical and radiotherapeutic methods of treatment of cancer of the lip, but of course these rates are not based on sufficiently standardized material to yield strictly comparable results. This is particularly the case with respect to radiotherapy by standardized methods in expert hands.

There would seem to be no question, however, as to the value of the chemosurgical method. The microscopic control of excision gives the method an unequaled advantage—"time after time, unsuspected outgrowths of small caliber, from the main tumor mass were found microscopically, at times extending a considerable distance after becoming grossly invisible." The method is practically without risk, it conserves lip tissue and it has no tendency to cause metastasis. As a rule regional metastasis must be removed by standard surgical dissection. "Chemosurgical treatment is particularly advantageous for cancer of the lip recurrent after surgical operation or irradiation. Such lesions often respond poorly to repetition of the original therapy, but they almost invariably respond to chemosurgical treatment." The chemosurgical method of treating cancer is another example of the value of expert specialization along a particular line. Further practical progress requires special training and facilities.

THE INTERNATIONAL LABOR ORGANIZATION ON SICKNESS INSURANCE

Possibly the action of the International Labor Organization at its twenty-sixth conference in Philadelphia during April and May of the present year may have a greater influence on sickness insurance legislation than any of the laws proposed in Congress.¹ Delegates from forty-one nations composed this conference, including nearly all Allied and neutral nations except the Soviet Union. There are four representatives from each nation. Two of these are appointed by the government, and one is chosen by employer and the other by labor organizations.

The recommendations for sickness insurance are more elaborate than those of any previous conference. They constitute a complete outline for legislation; if previous experience points to future possibilities, these recommendations are likely to be followed in legislation introduced in nearly all the countries not having sickness insurance at the present time. Some of the features in the recommended legislation especially suggested are as follows:

The medical care service should cover all members of the community, whether or not they are gainfully occupied.

All care and supplies should be available at any time and without time limit, when and as long as they are needed, subject only to the doctor's judgment and to such reasonable limitations as may be imposed by the technical organization of the service.

Complete and up to date technical equipment for all branches of specialist treatment, including dental care, should be available, and specialists should have at their disposal all necessary hospital and research facilities and auxiliary outpatient services such as nursing, through the agency of the general practitioner.

To achieve these aims, care should preferably be furnished by group practice at centers of various kinds working in effective relation with hospitals.

The working conditions of doctors and members of allied professions participating in the service should be designed to relieve the doctor or member from financial anxiety by providing adequate income during work, leave and illness and in retirement, and pensions to his survivors, without restricting his professional discretion otherwise than by professional supervision, and should not be such as to distract his attention from the maintenance and improvement of the health of the beneficiaries.

The professional supervision of the members of the medical and allied professions working for the service should be entrusted to bodies predominantly composed of representatives of the professions participating with adequate provision for disciplinary measures.

The central government agency should consult the representatives of the medical and allied professions, preferably through advisory committees, on all questions relating to the working conditions of the members of the professions participating, and on all other matters primarily of a professional nature, more particularly on the preparation of laws and regulations concerning the nature, extent and provision of the care furnished under the service.

Group medical service is recommended, and governments are urged to provide equipment for medical centers. The use of salaried physicians is recommended under certain circumstances.

1. International Labour Conference, Provisional Record, 26th Session, Philadelphia No. 30, *Social Security Bulletin* 7: 11 (June) 1944; *Monthly Labor Review* 59: 1 (July) 1944.

The health sections were adopted by a vote of 76 to 6, with 23 extensions. The attitude of one of the employers' representatives, Henry I. Harriman of the United States, who voted against the health section, was expressed as follows:²

The employers' group was frankly surprised at the universality of the demand for all-inclusive social security legislation. It was their feeling, as it is mine, that such laws must come as a matter of evolution and I personally voted against the final resolution, feeling that it went too far and too fast.

Now that I am back from Philadelphia and have had an opportunity to view the conference with better perspective, I feel that the employers of the United States must face the demand for enlarged social security and that if they are wise they will not try to stop the enactment of such laws but will guide them into sound and reasonable form.

Current Comment

POLITICAL CARE OF THE MENTALLY ILL IN NEW YORK

When an epidemic of amebic dysentery occurred in the Creedmoor State Hospital in New York in March 1943, Gov. Thomas E. Dewey appointed a commission to investigate the management and affairs of the Department of Mental Hygiene of the State of New York and the institutions operated by it. That report,¹ which has just been made available, emphasizes again the defects that seem inseparable from political medicine. In 1942 New York mental hospitals were caring for 83,053 patients at an annual cost of \$30,474,048.08. The commission found everywhere signs of inadequate examination of mental defectives, unsatisfactory recording of physical conditions on admission and lack of professional care, owing largely to the use of an undermanned professional staff. "The emphasis in all the institutions has been on administration at the expense of clinical medicine," says the report. This is the familiar criticism of all types of political medicine. In the mental hospital service in New York State advancement went to "careerists" and not to the psychiatrists of wide experience and knowledge. New methods of treatment such as shock and physical therapy disturbed the routine of the institutions and were therefore neglected. The report indicates that this service had not attracted competent physicians. Nurses were insufficient in numbers and defective in quality and were assigned to administrators and their families rather than to patients. The diets were monotonous and were not supervised by dietitians. Research and education were neglected or isolated in bureaucratic subdivisions apart from the treatment of patients. Here were all the apparently inevitable evils of mass medical treatment. Here were all the faults that usually accompany compulsory political care. Here, in miniature, is a picture of what the American people may expect if political medicine ever takes over general medical care in this country.

WALTER REED AND YELLOW FEVER

The investigations on tropical disease now being made all over the world focus attention again on the original experiments conducted under the direction of Walter Reed, which set the pattern for this type of study. In this war members of our armed forces have been decorated for their services as volunteers in the study of sandfly fever and other unusual conditions. When Reed and Carroll landed in Cuba in June 1900, Dr. Walter Reed came to live at the post hospital in Columbia Barracks. He found as executive officer on duty Lieut. Albert E. Truby, later retired as brigadier general. In 1943 General Truby assembled the records and reports of the Yellow Fever Commission and told the story which will be for all time one of the epics in the history of medicine.¹ The Reed board began its work on June 25, 1900. The story of the self sacrifice, the difficulties that they encountered, the tragedy of the death of Lazear have all been reflected in many a magazine article, in books, in plays and in motion pictures. The Truby account is exceptional because it is so fully documented and because it is really a first hand report. In view of the place that malaria has come to occupy in the present war, it is interesting to read in the annual report of General Leonard Wood to the Secretary of War, June 30, 1901, the following statement:

With the acquisition of our recent knowledge of the propagation of malarial fevers, it may be taken for granted that this preventable disease will be hereafter greatly reduced and, at most posts, practically eliminated. As an instance, for the week ending June 23, 1900 there were 34 cases of malarial fever under treatment at Rowell Barracks, Cuba (Cienfuegos). A year afterward, for the week ending June 22, 1901, chiefly in consequence of sanitary measures promoted by the post surgeon, Lieutenant A. E. Truby, there was not a single case.

HIGH COST OF VITAMIN THERAPY

Elsewhere in this issue (page 29) appears a statement from the Council on Pharmacy and Chemistry on the Comparative Cost of Vitamin Mixtures, which should help explain the \$179,000,000 spent for vitamins in 1943. Those who are familiar with the true indications for vitamin therapy already realize how many hundred million dollars are spent needlessly; others have only to glance at the Council's report. As the report reveals, the individual costs of vitamin mixtures vary greatly, almost as much as the promoted claims. No group of agents is now subjected to greater advertising abuse than vitamins. The radio, newspapers, store counters and other mediums constantly attract the ear and eye with pleas to improve the health, correct constipation, avoid dizzy spells and be successful with love and business affairs. How? Simply by taking vitamins according to the promoters! Fortunately there are bodies such as the Council on Pharmacy and Chemistry to set forth in succinct fashion the basic claims that may be made for vitamins. Such publications of the Council as New and Nonofficial Remedies present the scientifically recognized actions and uses of vitamins. This information should be spread widely.

MEDICINE AND THE WAR

ARMY

INVESTIGATION OF JAPANESE MEDICAL DEPOTS ON BIAK ISLAND

Captain Earl W. Schafer

Squadron Flight Surgeon

MEDICAL CORPS, ARMY OF THE UNITED STATES

In a previous report I submitted information concerning an investigation of Japanese medical depots at a recently evacuated air strip in New Guinea. On the beachhead at Biak Island I had the opportunity to investigate four Japanese medical depots. At this time the Japs were still holding the air strips on the island.

The depots were situated along a road leading from the beach and were in the most part intact. They were large huts with a thatched roof and metal sides. The supplies were all in wooden packing cases stacked neatly in piles.

In the previous report a number of drugs and evidence of certain laboratory and x-ray equipment were listed. In addition to the drugs seen on New Guinea there were atropine sulfate crystals, iodoform crystals, magnesium sulfate crystals, thrombogen (Fiji), digitaminum, stibnal solution in 20 cc. ampules, sodium citrate solution, glacial acetic acid, phenol, lead acetate and concentrated iodine solution. The drugs were identified by the English or Latin names on the containers in addition to the Japanese. There were many items which could not be identified, but the same precision in packing and the predominance of glass containers were noted.

One of the most interesting and speculative biologic preparations found was many packing cases full of ampules of male sex hormone. Anthrax vaccine and antitetic vaccine were found, also pound jars marked "Vitamin A and D Ointment" in large English letters.

Complete kits packed neatly with cotton in cardboard boxes 1 foot square, sealed in rubber bags and then tied with vines were noted in great numbers. Two of these kits were packed in a heavy wooden box. The kits contained a variety of drugs, bandages, intravenous saline solution (500 cc.), a quart of alcohol, a small rectangular metal box with a 20 cc. glass syringe and needles. The latter were each placed in the end of a small metal tube, two needles to the tube.

Because of high cliffs honeycombed with caves and close to the beachhead, large numbers of Japanese soldiers were able to withdraw into these natural fortresses. Later after artillery and naval bombardment, dive bombing, strafing and flame throwers were employed the majority of the enemy were disposed of. Medical supplies were found in many of the caves.

Quantities of saki and Kirin beer were captured. The quartermaster gave one issue of the latter to each of the units. The product proved to be as palatable as any American brand in the long long ago.

NEW NAME IS SELECTED FOR MORALE SERVICES DIVISION

The name of the Morale Services Division, Army Service Forces, has been changed to the Information and Education Division in order to describe more accurately its increasingly important functions. There will be no change in functions or personnel. First established in 1940 as a branch of the Adjutant General's Office, the Information and Education Division is now providing a worldwide service of information to troops as well as off duty educational programs. In addition to its headquarters in Washington, D. C., the division maintains offices in New York City and in Los Angeles. Its military personnel are in every theater where our troops are stationed.

The division, under the direction of Major Gen. Frederick H. Osborn, is charged with the planning and supervision of matters not pertaining to command which relate to the maintenance and improvement of morale within the Army. It conducts research studies through attitude surveys and performance

data designed to furnish information to serve as a guide in problems of military leadership. It supervises the publication of *Yank*, the army weekly, and 2,023 other army newspapers, operates the largest correspondence school in the world, the United States Armed Forces Institute, which is helping 225,000 men and women of all the armed services prepare themselves for better jobs on their return to civilian life, and produces forty-two hours of transcribed entertainment and educational radio programs weekly for use by more than four hundred overseas radio outlets.

In addition, the Information and Education Division produces and distributes information and educational movies, directs army orientation courses and off duty discussion programs and prepares "short guides" to foreign countries to which our troops may be sent.

ARMY AIR FORCES CONFERENCE ON RHEUMATIC FEVER

A recent conference on rheumatic fever was held by the Army Air Forces in Denver. The objectives of the meeting were outlined by Col. William P. Holbrook, chief, Professional Division, Office of the Air Surgeon. Colonel Holbrook also discussed some of the unsolved problems of rheumatic fever which must be met during the next year. The report of the Committee on the Prophylactic Use of the Sulfonamides indicated that these drugs should be used in treatment only as a last resort and that their principal indication is for prophylaxis. The report of the Committee on Criteria for the Diagnosis of Rheumatic Fever contained recommendations based principally on the paper given by Dr. T. Duckett Jones at the Chicago session of the American Medical Association in June. The important recommendations of the Committee for Standardization of Convalescent Care of Rheumatic Fever were that no patient should be discharged to duty until he had actually undertaken duty under supervision in the convalescent center and that this duty should be in accord with his military occupational specialty.

PRISONERS OF WAR

Major Edwin S. Kagy is a prisoner of war of the Japanese and is now in a prison camp in Tokyo. Dr. Kagy is a graduate of Tulane University of Louisiana School of Medicine, New Orleans, in 1934. He was commissioned in the regular Medical Corps of the Army in August 1935 and was ordered to the Philippines in the fall of 1940. He was at Corregidor when Bataan fell and was taken prisoner. In the fall of 1943 he was transferred from the Philippines to Tokyo.

Lieut. Edwin Tucker, formerly of New Orleans, has been a prisoner of the Japanese since the fall of Bataan. Dr. Tucker graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1936 and entered the service July 2, 1941.

Capt. Peter C. Graffagnino, who was recently reported missing, is now a German prisoner. Dr. Graffagnino is a graduate of Tulane University of Louisiana School of Medicine, New Orleans, 1939. He entered the Army Medical Corps in September 1941.

COLONEL BLECKWENN APPOINTED NEUROPSYCHIATRIC CONSULTANT

Col. William J. Bleckwenn, professor of neuropsychiatry at the University of Wisconsin Medical School, Madison, has been appointed as the neuropsychiatric consultant to the Sixth Service Command with headquarters in Chicago. Dr. Bleckwenn recently returned from a period of over two years' service in the South Pacific, having gone out in command of a medical regiment. Later he served as a base area surgeon. He graduated from Columbia University College of Physicians and Surgeons, New York, in 1920 and entered the service Jan. 13, 1941.

TWO THIRDS OF ARMY WOUNDED RETURNED TO DUTY

According to a recent release, fully 96 per cent of all men wounded on battlefields recover, and of these about two thirds return to duty. When the convalescent period is reached the Army's new intensive program of reconditioning begins. This includes planned, progressive physical exercise to speed the recovery of strength and stamina. Occupational therapy encourages normal habits, and educational therapy mental advancement. Following the reconditioning program the men who have recovered but who do not meet the Army's physical standards for general service may remain in the Army in limited service status or in some cases may return to civilian life. Twenty-three per cent of those discharged from hospitals with serious physical limitations, and who were given the option of discharge from the Army, elected to remain in the military service, according to War Department figures for the period from June 25 to July 25. Continued hospital care as required will be available to casualties returned to civilian life, together with opportunity for vocational rehabilitation or academic advancement through study in schools and colleges, depending on circumstances and personal choice.

ARMY OPENS MALARIA TREATMENT CENTER

The Moore General Hospital, Swannanoa, N. C., has been designated a medical center for the study and treatment of tropical diseases under the command of Lieut. Col. Joseph M. Hayman of Cleveland. It was opened on September 1. There are 350 beds in this center for patients who are receiving active treatment, and in addition there are barracks facilities for 1,100 men for the reconditioning program. On release from bed treatment the patients will be transferred to the reconditioning barracks and continue any further treatment required in addition to the training needed to prepare for active duty again. As far as possible all tropical disease patients in the Army will be concentrated at the new center. Particular attention will be paid to malaria and filariasis. Facilities for expansion of bed capacities as required are being provided. The new center will be under the supervision of Lieut. Col. Francis R. Dieuaide, chief of the Tropical Disease Branch of the Medicine Division of the Surgeon General's Office, headed by Brig. Gen. Hugh J. Morgan.

CONSERVATION OF MEDICAL CORPS OFFICERS

The Adjutant General of the Army has recently issued a circular that will effect the strictest economy in the utilization of Medical Corps officers.

Tables of organization are changed by this order so that many positions that do not require the professional knowledge or skill of medical officers may now be filled by properly qualified Medical Administrative or Sanitary Corps officers. Such changes refer largely to duties of an administrative, executive or training nature.

Under the new provisions it is believed that Medical Corps officers will be more fully utilized for their technical knowledge and professional skill than in the past.

CAPTAIN ROBERT WARE MISSING

Capt. Robert B. Ware, formerly of Lynchburg, Va., has been reported missing in action since D day. Dr. Ware graduated from the Medical College of Virginia, Richmond, in 1940. He volunteered for duty and was called July 1, 1940. He attended officers' school at Carlisle Barracks, Pennsylvania, and has been overseas since Sept. 27, 1942.

MEDICAL DEPARTMENT ANNIVERSARY

The Army Medical Department observed on July 27 its 169th anniversary of the establishment of the first medical service for the American Army. The Medical Department had its inception in the creation by the Continental Congress on July 27, 1775 of a hospital for the American forces shortly after George Washington assumed command in the Revolutionary War.

ARMY AWARDS AND COMMENDATIONS

Colonel Edward J. Tracy

The Legion of Merit was recently awarded to Col. Edward J. Tracy, formerly of Albuquerque, N. M. The citation accompanying the award read "For service as Surgeon, VIII Bomber Command, from Aug. 11, 1942 to Jan. 6, 1944. He directed the expansion of medical service for personnel of this command from one group to a large number of groups. Through his foresight and initiative he overcame the problems of sanitation and care and evacuation of casualties which arose from this rapid expansion during a relatively short period. He instituted the policy of flight surgeons accompanying their units on operational crews under their care. He himself participated in several operational missions in order to gain information and better to evaluate the stress and strain to which combat personnel are subjected. The immediate knowledge gained by him enabled him to make recommendations to the commanding general, VIII Bomber Command, as to the limits imposed by the human factor and as to the policies to be adopted on leaves, passes and furloughs and related matters affecting morale. He also kept abreast of modern methods of treatment and use and care of protective flying equipment, applying these new methods whenever practicable. The initiative, skill and sound judgment displayed by him have contributed immeasurably to the combat achievement of the VIII Bomber Command." Dr. Tracy graduated from the University of Minnesota Medical School, Minneapolis, in 1930 and entered the service after graduation from the Army Medical School in 1932.

Captain Joseph E. Sokal

The Bronze Star Medal was recently awarded to Capt. Joseph E. Sokal for "meritorious achievement in connection with military operations against the enemy at Makin Atoll, Gilbert Islands, Nov. 20-21, 1943. Captain Sokal set up an aid station under extremely adverse conditions and under constant enemy sniper fire. From this position he administered medical treatment to approximately 100 men. He was tireless in his efforts to aid the wounded and by his diligent application of professional skill saved many lives." Dr. Sokal graduated from Yale University School of Medicine, New Haven, Conn., in 1940 and entered the service after completion of his internship in 1941. Besides the Gilbert Islands campaign he took part in the recent landing of Saipan. Dr. Sokal was also commended for his loyal cooperation, untiring zeal and unselfish devotion to duty during the Gilbert campaign; he has also been cited for the Silver Star.

Captain William E. Nunnery

The Soldier's Medal was recently awarded to Capt. William E. Nunnery "for heroism at March Field, California, on Feb. 1, 1944, when an army airplane made a forced landing and caught fire. An officer of the combat crew was pinned in this airplane. An explosion of the gas tanks was expected at any minute. Captain Nunnery, who was approximately 300 to 500 yards from the scene of the airplane at the time of its crash, immediately proceeded thereto and on arriving at the then burning airplane heroically and with utter disregard for his own safety assisted in extricating an officer crew member who was trapped and seriously burned." Dr. Nunnery graduated from the University of Kansas School of Medicine, Kansas City, in 1942 and entered the service in July 1943.

Captain Benjamin I. Schneiderman

Capt. Benjamin I. Schneiderman was recently awarded the Bronze Star. The citation that accompanied the award read in part "For heroic achievement in the action of 12 February 1944 near Anzio, Italy. During an enemy air attack on the Anzio-Nettuno beachhead area, Captain Schneiderman remained at his post of duty even though flak was falling throughout the hospital. Disregarding the extreme danger, he performed one operation after another. Bombs fell in the hospital area and shell fragments pierced the operating tent, yet he continued to perform his duties in a cool and efficient manner. His courage and devotion to duty reflect credit on himself and the Medical Corps." Dr. Schneiderman graduated from New York University College of Medicine, New York, in 1939 and entered the service in May 1942.

NAVY

NAVAL HOSPITAL IN ENGLAND TREATS
HUNDREDS OF WOUNDED FIRST
TWO WEEKS OF INVASION

At a U. S. naval hospital in England, several hundred U. S. casualties from France were treated with the loss of only 1 man. Formerly a British hospital, this institution is a quarter of a mile long, is three stories high with more than a hundred wards, operating rooms and laboratories, and is maintained in a state of constant readiness. Sixty outbuildings can be utilized in emergencies, almost doubling the normal capacity. The hospital maintains a staff of 50 doctors, 12 hospital corps officers serving as technicians, 98 trained navy nurses and 400 skilled hospital corpsmen. Another 180 men are engaged in maintenance. On D day the supply of medicine and drugs included 537,500 cc. of plasma, 398,500 cc. of other intravenous solutions, 794 gallons of alcohol, 50,000 tablets of sedatives of various types, 143,500 sulfonamide tablets and 71 pounds of sulfonamide powders, 50,300,000 units of penicillin, 299 pints of medicinal whisky, 4,958 bandages of all types, plus orthopedic equipment including 5,326 pounds of cotton, 2,500 pounds of plaster of paris, 100,000 yards of crinoline and 200 rolls of sheet wadding.

Each casualty on arrival at this hospital is examined separately by the chiefs of surgery, medicine and neuropsychiatry to determine as quickly as possible the preliminary treatment necessary and whether surgery is needed. After preliminary examinations and treatment each man is bathed, shaved, issued clean clothes and put into a clean, comfortable bed in rooms staffed twenty-four hours a day.

Complete arrangements for the transfer of this hospital from British to American hands began last fall, when Rear Admiral Luther Sheldon Jr., Medical Corps, U. S. N., assistant chief of the navy's Bureau of Medicine and Surgery, arrived in the United Kingdom. Early in the spring Capt. C. J. Brown, formerly of Philadelphia, brought his staff over to assume command. Capt. J. W. Miller, formerly of Washington, D. C., is executive officer. Other members of the medical corps on the staff are Capt. James M. Faulkner, Brookline, Mass., chief of medicine; Capt. A. H. Weiland, Coral Gables, Fla., chief of orthopedic surgery; Comdr. Henry W. Hudson, Waban, Mass., chief of surgery, and Comdr. Robert T. Baldridge, Providence, R. I., chief of the urology department.

MEDICAL COMPANY COMMENDED FOR
MERITORIOUS SERVICE

Company C, Third Medical Battalion, attached to the Third Marine Division, Reinforced, in the capture of a beachhead on Bougainville Island, has been commended by Major Gen. Roy S. Geiger, U. S. Marine Corps, commanding general of the First Marine Amphibious Corps. The citation reads "During the military operations commencing Nov. 1, 1943, which resulted in the capture by the Third Marine Division, Reinforced, of a beachhead on Bougainville Island, British Solomon Islands, Company C, Third Medical Battalion, made conspicuous and valuable contributions to the success of our arms. At the battles of Cape Torokina, Koromokina Lagoon, the Coconut Grove, Piva, Piva Forks and Fry's Nose, as well as during enemy bombing attacks and combat operations of a minor nature, the personnel of the company brought aid to the wounded under the most adverse conditions of weather and jungle terrain, cheerfully enduring enemy fire throughout each of these actions and frequently risking their own lives in order to evacuate and administer medical assistance to the injured during the heat of combat. The officers and men of the company acquitted themselves gallantly, winning the admiration of the combat troops and saving the lives of hundreds of the wounded."

The commanding officer of the company was Lieut. Comdr. Rodney Robert Gleysteen. Dr. Gleysteen graduated from the State University of Iowa College of Medicine, Iowa City, in 1938 and entered the service Aug. 15, 1941.

Other Medical Corps officers with this company were Lieut. Leo John Koscinski, Chicago, who graduated from Northwestern University School of Medicine, Chicago, in 1941 and entered the service April 13, 1942; Lieut. Charles Reid Goodwin, Port Arthur, Texas, who graduated from the University

of Texas Medical Branch, Galveston, in 1940 and entered the service in October 1942, and Lieut. Frederick Gordon Grant, Scotia, N. Y., who graduated from the University of Rochester School of Medicine and Dentistry, New York, in 1940 and entered the service in September 1942.

NAVAL HOSPITAL PROGRAM TO
BE EXPANDED

Southern California, the Navy's largest medical center with more than 17,000 navy marine and coast guard men as patients in hospitals in this area, has an expansion program under way, including recommissioning of former navy hospitals at Spadra, Beaumont and Banning. In anticipation of increased intensity in Pacific warfare, additions are being made at several of the navy hospitals in southern California and work is under way to recommission the former army hospitals at Spadra, Beaumont and Banning. The three convalescent hospitals at Spadra, Beaumont and Banning now are being made ready for more than 3,000 patients. The hospital at Spadra will be commanded by Capt. Harold L. Jensen as an annex to the Corona hospital, also under his command. Spadra was formerly a state medical center. It has been adapted for service use with several temporary buildings added to the permanent structures erected by the state. The Corona hospital, formerly a luxurious hotel, is one of the nation's most beautiful medical centers. It has been named the rheumatic fever center for the Navy and is the largest navy tuberculosis center on the West Coast. An almost separate hospital within the hospital has been opened to treat cases of tuberculosis.

NAVY AWARDS AND COMMENDATIONS

Lieutenant William B. Neal Jr.

The Navy and Marine Corps Medal was awarded to Lieut. William B. Neal, formerly of Chicago, "for distinguishing himself by heroism while attached to the U. S. S. *Lansdale* during and following an attack by enemy aircraft off the coast of Algeria on the night of April 20, 1944. When the *Lansdale* was damaged and the ship subsequently sank, Lieutenant Neal was severely injured by the shock of the initial explosion but promptly commenced rendering first aid to other casualties of the disaster. With great skill and the utmost fortitude, he continued administering medical assistance until after the order had been given to abandon ship. When removed from the water by a rescue vessel he was completely exhausted but within a short time resumed his untiring efforts to revive survivors and care for the wounded for over thirty-six hours, at which time it became necessary to hospitalize him. He undoubtedly contributed to the saving of several lives. The extraordinary courage, selflessness and devotion to duty displayed by Lieutenant Neal were in keeping with the highest traditions of the Naval Service." Dr. Neal graduated from the University of Chicago School of Medicine in 1941 and entered the service in August 1943.

Commander Emil Edward Napp

Comdr. Emil Edward Napp, formerly of New Rochelle, N. Y., was awarded the Silver Star Medal "for conspicuous gallantry and intrepidity as a regimental surgeon during the seizure and occupation of Japanese held Cape Gloucester, New Britain, from Dec. 26 to 31, 1943. Accompanying assault troops into the zone of action on numerous occasions throughout this hazardous period, Commander Napp repeatedly risked his life in order to care for injured personnel and supervise their evacuation from front lines to battle aid stations, in one instance ministering medical aid to a wounded marine while pinned down by Japanese sniper fire. By his keen foresight in anticipating material needs of casualties in the field of battle and his outstanding skill, Commander Napp contributed to the saving of many lives. His professional integrity and daring courage in the face of grave peril were in keeping with the highest traditions of the United States Naval Service." Dr. Napp graduated from New York Medical College, Flower and Fifth Avenue Hospitals, New York, in 1933 and entered the service June 9, 1941.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Combined Wartime Graduate Medical Meeting and Regional Meeting of the American College of Physicians, Hotel Vancouver, Vancouver, B. C.: The Recent Status of Rickettsia Disease, Dr. Matthew Riddle; Control of Staphylococcal Infections with Sulfonamide Drugs, Lieut. Col. Roy H. Turner; Clinical Experience with Penicillin, Capt. Charles E. Watts; Some Pharmacologic Problems in the Use of Chemotherapeutic Drugs, Dr. Norman D. Davis; luncheon address, Major Gen. G. R. Pearkes; Respiratory Limitations in Altitude Flying, Group Capt. G. E. Hall; Respiratory Disease Problems in an East Coast Base, Surg. Comdr. J. Wendell MacLeod; Visualization of the Chambers of the Heart and Great Vessels, Lieut. Comdr. Israel Steinberg; Experimental and Clinical Aspects of Carotid Sinus Reflexes, Dr. Hance Haney; dinner addresses, Dr. David P. Barr and Comdr. Corydon M. Wassell, September 14.

Hepatitis, Lieut. Col. Roy H. Turner; Psychosomatic Medicine, Brig. Gen. W. P. Warner; Gastroenterological Problems in the Canadian Navy, Surg. Comdr. J. Wendell MacLeod; Some Principles and Problems in Immunity, Dr. C. E. Dolman; Thiouracil in Graves' Disease, Dr. David P. Barr; Body Section Radiography, Comdr. Wendell G. Scott; Maintenance of Normal Body Temperature in Service Personnel, Group Capt. G. E. Hall; Some Experience with the Use of Gold Salts in the Treatment of Arthritis, Dr. P. H. Sprague; Observations on Active Rheumatic States, Dr. John MacEachern; Malaria Control (with two films), Lieut. Comdr. Frank P. Mathews, September 15.

Rhoads General Hospital, Utica, N. Y., in conjunction with the fifth district branch of the Medical Society of the State of New York: Tuberculosis, Drs. Ethan Flagg Butler and S. Eric Simpson; Chest X-Rays in Industry, Dr. William C. Jensen; Tuberculosis in Military Service, Capt. Daniel J. Feldman; Rehabilitation address, Dr. Herbert H. Bauckus; Rehabilitation of the War Veteran, Dr. Roy Woodward; motion picture demonstration, "Psychology in Action," September 19.

At Mayo General Hospital, Galesburg, Ill.: Diseases of the Kidneys and Urogenital Tract, Drs. Francis D. Murphy and Wilbur E. Post and Lieut. Col. Harold C. Lueth, September 20.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, August 26, page 1197)

CALIFORNIA

Santa Monica Hospital, Santa Monica. Capacity, 220; admissions, 7,970. Mr. Ritz E. Heerman, General Manager (5 interns).

ILLINOIS

Belmont Community Hospital, Chicago. Capacity, 125; admissions, 3,778. Miss Gertrude F. Scofield, Superintendent (interns).
Elgin State Hospital, Elgin. Capacity, 4,946; admissions, 1,495. Dr. Charles F. Read, Managing Officer (residents—psychiatry).
Peoria State Hospital, Peoria. Capacity, 2,708; admission, 765. Dr. Joseph H. Ellingsworth, Medical Superintendent (residents—psychiatry).

NEW YORK

Harlem Eye and Ear Hospital, New York City. Capacity, 50; admissions, 1,719. Dr. Charles B. Meding, Executive Surgeon (resident—ophthalmology-otolaryngology).
Sydenham Hospital, New York City. Capacity, 247; admissions, 4,619. Miss Fanny Fried, Executive Secretary (interns—2 October, 2 November, 2 December).

PENNSYLVANIA

Chester County Hospital, West Chester. Capacity, 178; admissions, 3,442. Mr. Alton F. Reichgert, Director (2 interns).

TENNESSEE

Davidson County Tuberculosis Hospital, Nashville. Capacity, 300; admissions, 328. Dr. R. R. Crowe, Superintendent (2 residents—tuberculosis, July 1945 to March 1946).

VIRGINIA

Alexandria Hospital, Alexandria. Capacity, 175; admissions, 4,474. Mr. R. G. Whitton, Superintendent (3 interns).

WARREN F. DRAPER PROMOTED TO MAJOR GENERAL

Announcement has just been made of the promotion of Brig. Gen. Warren F. Draper to the rank of major general. General Draper, a graduate of Harvard Medical School, Boston, in 1910, began as assistant surgeon, United States Public Health Service, in that year. During the first world war he was assigned to the Army and had charge of extracantonment sanitation in the Norfolk, Va., area. Since then he has served as assistant surgeon general in charge of the states relation division of the Public Health Service, and for three years he served as state health officer of Virginia. In 1939 he was named assistant to the Surgeon General under Dr. Thomas Parran and later became deputy surgeon general. In the spring of this year he was assigned to duty with the Army in the grade of brigadier general at the request of Hon. Henry L. Stimson, Secretary of War. At present General Draper is chief of the public health branch of civil affairs in the European theater. This branch is responsible for the care of ill and injured civilians in the battle area, helps distribute medical supplies and gives advice on prevention and control of disease among civilians and animals. General Draper was a member of the House of Delegates of the American Medical Association from 1925 to 1943 inclusive.

PUBLIC HEALTH UNDER HITLER

For the first time during the war Reich Health Leader Dr. Conti on May 24, according to DNB, addressed a large gathering of men and women medical students of Freiburg University when he spoke on the problem of recruiting for the medical profession. He drew a picture of the aims and tasks which today just after the victorious conclusion of the war face the future members of the medical profession in the spheres of public health, racial and population policy, and the guidance of the people from a purely scientific medical point of view. His statements, in which he drew a parallel between the profession of doctor and the young medical student of the period after the first world war and today, culminated in an appeal to make a substantial and energetic contribution to solving all problems arising in this struggle, which is a necessity of fate.

Referring in particular to future doctors, Conti emphasized that however great the number of new men and women doctors, we shall always need them. The postwar tasks in all the various fields of public health are so numerous that we can never have enough doctors. (Freiburg University has put a ban on admission to a number of other faculties.) After the war the German people will see a new upward development in the numbers of all population too which will put into the shade all previous experience. The basis of nutrition, which is closely connected with that of the health policy of the German nation, is completely safeguarded and all our enemies' hopes for a collapse have come to naught, for the victory in which we believe remains ours.

According to *Völkischer Beobachter* of April 23, 1944 (Germany) as part of the work of the RDF, the Office for Racial Policy, in agreement with the party chancellery, has founded a marriage bureau. It started as a correspondence center of the RDF first of all in Dresden. In view of the excellent results achieved in Saxony, a Rhineland branch of the correspondence center was recently opened in Strasbourg, Danzig, Frankfurt on the Main, Munich, Graz, Vienna, Hanover and Berlin. The Cologne correspondence center is under the direction of the head of the Office of Racial Policy of the Gau Administration Köln-Aachen, Oberbereichsleiter Merzenich.

Nieuwe Rotterdamsche Courant of April 14, 1944 (Netherlands) publishes figures for cases of contagious diseases reported during the week March 19-25 inclusive: diphtheria 1,427 (Amsterdam 172, Rotterdam 164), scarlet fever 800 (Amsterdam 176, Rotterdam 73), infantile paralysis 13 (Hennaardera-deel 4).

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

Aug. 28, 1944.

Recent Developments in Emergency Medical Service

Through their voluntary organization to meet disasters and emergencies under the Emergency Medical Service of the Office of Civilian Defense, doctors throughout the nation have demonstrated their ability to serve in time of disaster. Their work in the Hartford circus fire is one recent striking example. While the OCD budget has been reduced from some \$4,000,000 last year to \$778,000 for 1944, its voluntary program carries on, and there is indication that its emergency medical program is one form of voluntary organization that will continue after the war.

The OCD medical program has of late been under the direction of a U. S. Public Health Service doctor, Senior Surgeon John J. Bourke. As medical assistant to the director of civilian defense, Lieut. Gen. William N. Haskell, he has been responsible for much of the planning that has prompted recent developments. Most significant of these was the appointment of Public Health Service commissioned officers assigned to the service commands of the Army as liaison officers, to be available, in addition to their regular duties, as medical field representatives of the Office of Civilian Defense. Their new duties will be to assist the states in all Emergency Medical Service problems.

Because of budget limitations of OCD the services of medical officers in the nine civilian defense regions were terminated. As a result, General Haskell requested Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, to make the liaison officers available for OCD duty if needed. Dr. L. H. Thompson, Assistant Surgeon General of the U. S. Public Health Service, has pointed out that the new duties will involve dealings with the medical assistant to the director of OCD, with the state chiefs of Emergency Medical Service, the officers of the service commands in matters pertaining to Emergency Medical Service.

A word about the background of the Emergency Medical Service program of the Office of Civilian Defense: For several years, volunteer organizations had been developed in fire and police services. Since EMS has more recently been developed, it has provided competent medical relationship in the community,

assisted by an advisory committee representing the various responsible agencies such as the medical profession, hospital groups, nursing organizations and the Red Cross. It has provided a "relatively safe" type of field operation which allows for the use of specially trained volunteers in the field of first aid and rescue.

What is said to be even more important from the standpoint of prospective patients in a disaster is a coordinated central control which tends to prevent the overloading of any one institution beyond its capacity as to bed space and professional or specialized service. The internal organization and planning which have taken place within the hospitals as part of the Civilian Defense program have tended to develop competent medical teams under physician and nurse supervision to report promptly to the scene of the accident, while other professional groups within the hospital are assigned specific duties following the reception of patients which will allow them to exercise special skills in surgery, shock, resuscitation, burn therapy and fracture work to the ultimate advantage of the patient's recovery. The work of the local chief of Emergency Medical Service and his advisory committee has provided a careful, unbiased appraisal of the medical facilities.

The nine Public Health Service commissioned officers now with the army service commands as liaison officers, who will also act as field representatives of OCD, are:

Sr. Surgeon O. F. Hedley, Liaison Officer, U. S. P. H. S., First Service Command, 808 Commonwealth Avenue, Boston.

Sr. Surgeon Albert W. Russell, Liaison Officer, U. S. P. H. S., Second Service Command Headquarters, Governors Island, N. Y.

Sr. Surgeon Fred W. Kratz, Liaison Officer, U. S. P. H. S., Third Service Command Headquarters, U. S. Post Office and Courthouse, Baltimore.

Medical Director Joseph Bollen, Liaison Officer, U. S. P. H. S., Fourth Service Command, Post Office Building, Atlanta, Ga.

Surgeon Charles F. Blankenship, Liaison Officer, U. S. P. H. S., Fifth Service Command, Fort Hayes, Columbus 18, Ohio.

Sr. Surgeon Adolph S. Rumreich, Liaison Officer, U. S. P. H. S., Sixth Service Command, 2129 Civic Opera Building, 20 North Wacker Drive, Chicago 6.

Medical Director L. O. Weldon, Liaison Officer, U. S. P. H. S., Seventh Service Command, Federal Building, Omaha.

Medical Director K. E. Miller, Liaison Officer, U. S. P. H. S., Eighth Service Command, Fort Sam Houston, San Antonio, Texas.

Medical Director W. T. Harrison, Director Ninth U. S. P. H. S., Service District, 1223 Flood Building, San Francisco.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—A subcommittee of the House Committee on Labor has initiated hearings to investigate the aid given to the physically handicapped, pursuant to H. Res. 230 adopted by the House of Representatives in June 1944. Representative Kelley of Pennsylvania is chairman of the subcommittee. The other members are Representatives Randolph, West Virginia, Worley, Texas, Scanlon, Pennsylvania, Welch, California, Day, Illinois, and Baldwin, New York. The initial hearing was scheduled for the period extending from August 29 to August 31, at which time testimony was received with respect to the blind. A subcommittee of the House Committee on Civil Service has been conducting hearings on H. R. 4909, a bill to provide health programs for government employees. Among the witnesses who testified at the hearings were War Manpower Commissioner Paul V. McNutt, Civil Service Commissioner Arthur S. Fleming, Brigadier General Hines, Veterans Administrator, Surgeon General Parran, United States Public Health Service, Dr. Victor G. Heiser, Medical Consultant of the National Association of Manufacturers, and Dr. Carl Peterson, Secretary of the Council on Industrial Health of the American Medical Association. H. R. 5125 has passed the Senate, with numerous amendments, proposing to establish a Surplus War Property Administration and to provide for the proper disposal of surplus war property. One section assigns to veterans, including physicians and dentists, suitable preferences to the extent feasible in

acquisition of types of surplus property useful in carrying on the business or professional activity of the veteran. In the discussion of this section on the floor of the Senate, reference was made to the fact that many physicians and dentists sold their "businesses to go into the armed forces when they were called."

Bills Introduced.—H. R. 5171, introduced by Representative Dingell, Michigan, provides that, under the rules and regulations prescribed by the Secretary of War, the Surgeon General of the Army will be authorized and directed to appoint as second lieutenants in the Medical Department of the Army enlisted men who have served three years or more in such department. H. R. 5172, introduced by Representative Dingell, Michigan, provides that under rules and regulations prescribed by the Secretary of the Navy the Surgeon General of the Navy will be authorized and directed to appoint as ensigns in the Medical Department of the Navy enlisted men who have served three years or more in the Hospital Corps. H. R. 5173, introduced by Representative Harless of Arizona, provides that any enlisted man in the Medical Department of the Army who is serving or shall have served in a combat area during the present war shall be paid additional compensation at the rate of \$10 per month for the period beginning as of the date of the commencement of such service or as of Jan. 1, 1944, whichever date is the later, and ending six months after the date of the cessation of hostilities as proclaimed by the President.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Dr. McLester Named Chairman of Hospital Board.—Dr. James S. McLester, Birmingham, has been named chairman of a five member administrative board of hospitals which is to meet twice a month to administer operation of Jefferson and Hillman hospitals within the pattern of the University of Alabama School of Medicine, Birmingham. The position of chairman will be occupied by a member for one year, rotating among other members, according to vote of the board in a recent meeting with members of the Jefferson County Commission and Raymond R. Paty, LL.D., president of the university. Dr. McLester will serve as chairman until Dec. 31, 1945. Other members of the board are Judge Gardner F. Goodwyn Jr., Bessemer, vice chairman, E. A. Lowe, secretary, and Dr. Harry I. Jackson, Thomas W. Martin and Edward Norton, all of Birmingham.

CONNECTICUT

Clinical Congress.—The twentieth clinical congress of the Connecticut State Medical Society will be held at the New Haven Lawn Club, New Haven, September 28-29. Among the speakers will be:

- Dr. William B. Terhune, New Canaan, Psychiatric Problems of the Returning Soldier.
- Dr. John R. Paul, New Haven, Infectious Hepatitis.
- Dr. Harry Gold, New York, How to Choose the Correct Digitalis Preparation.
- Dr. Joseph E. F. Riseman, Boston, The Modern Treatment of Angina Pectoris.
- Lieut. Col. Herrman L. Blumgart, M. C., The Relation of Effort to Myocardial Infarction.
- Dr. Robert H. Williams, Boston, Thiouracil in the Treatment of Hyperthyroidism.
- Dr. Robert M. Yergason, Hartford, Metallic Fixation of Fractures by the Use of Recently Devised Methods and Appliances: Special Reference to Kirschner Wire, Vitallium Screws, Tantalum Foil and Plates.
- Dr. Herman E. Pearse Jr., Rochester, N. Y., Recent Advances in Common Duct Surgery.
- Dr. Arthur J. Geiger, New Haven, Bacterial Endocarditis.
- Dr. Joseph Kreiselman, Washington, D. C., Resuscitation.
- Dr. Kenneth W. Thompson, New Haven, Present Trends in the Treatment of Varicose Veins.
- Dr. Julian B. Herrmann, New York, Recent Advances in the Treatment of Cancer of the Breast.
- Dr. John J. Morton Jr., Rochester, Progress in Cancer Research.

One afternoon session will be devoted to a symposium on penicillin medicine and surgery by Dr. Francis G. Blake, dean and professor of medicine, Yale University School of Medicine, and his staff and Dr. Samuel C. Harvey, professor of surgery at Yale, and his staff. A second afternoon session will be devoted to demonstrations in the treatment of burns at the New Haven Hospital and the care of extremities with deficient arterial circulation.

FLORIDA

Personal.—Dr. Robert G. Nelson, Tampa, has been appointed a member of the state board of medical examiners to succeed Dr. William M. Rowlett, Tampa, resigned.

Food Handlers Educational Program.—Arrangements are being made by the Jacksonville Health Department, in cooperation with the state and county department of vocational education, to start a perpetual food handlers educational program the early part of September. The program will be a twelve hour course, comprising six meetings each two hours in length and is designed to meet the practical needs of food handlers.

ILLINOIS

Chicago

Anton Carlson Honored.—The July issue of *Gastroenterology*, the official journal of the American Gastroenterological Association, was dedicated to Dr. Anton J. Carlson, recipient of the association's Friedenwald Medal for 1944 and emeritus professor of physiology, University of Chicago School of Medicine, since 1940. In addition to carrying scientific material, the journal includes editorial tributes to Dr. Carlson.

University News.—Major General George F. Lull, deputy surgeon general, U. S. Army, will be the principal speaker

at the graduation exercises for the class of 1944 at Northwestern University Medical School in Thorne Hall, September 14, at 4 o'clock. Admission will be by invitation only. After the exercises the medical division of the alumni association will hold a reception in Thorne Hall for the graduating class, faculty members and their families.

Institute for Hospital Administrators.—The Chicago Institute for Hospital Administrators will be held at International House, University of Chicago, September 11-22. This year for the first time the institute will be conducted by the American College of Hospital Administrators instead of by the American Hospital Association. Dr. Malcolm T. MacEachern will be director of the institute, a position he has held since it was started twelve years ago. Additional information may be obtained from the American College of Hospital Administrators, 18 East Division Street.

Fernel Named in Violation of Drug Act.—Dr. Jean Paul Fernel was named August 21 in a criminal information filed before Federal Judge Michael L. Igoe that charged twenty-three counts of violating the Federal Food, Drug and Cosmetic Act. The action alleged that Dr. Fernel had engaged in a mail order business "purveying medical preparations that the government charges are misbranded," according to newspaper reports. It is further stated that Dr. Fernel was found guilty last November of similar charges (*THE JOURNAL*, Nov. 27, 1943, p. 849), was sentenced to one year in the county jail and was fined \$500. He is said to be now out on bail pending an appeal to the U. S. Circuit Court of Appeals.

KENTUCKY

Tuberculosis Commission Appointed.—Governor Simeon S. Willis on July 31 named a commission of eleven men and one woman to inaugurate Kentucky's first statewide program of tuberculosis treatment and control. Primary task of the commission will be to select sites for five tuberculosis sanatoriums authorized by the 1944 legislature. Initial phases of the program will be financed by \$1,500,000 which the legislature ordered taken from the state treasury's surplus and invested in war bonds until contracts can be let for construction work. Three members of the commission are Drs. Gaiethel L. Simpson, Greenville; Omer F. Hume, Richmond, and Carl C. Howard, Glasgow. Eight members were named from the public at large. Dr. Philip E. Blackerby, Louisville, commissioner of health of Kentucky, was named to a four year term by virtue of his office. Members draw no pay or personal expenses. The 1944 act divided the state into six districts and specified that a sanatorium must be located in each of them, excepting only the Louisville district, which is already served by the State Tuberculosis Sanatorium (Hazelwood), Louisville. The five remaining districts are drawn to serve the west, north, northeastern, southeastern and south central sections of the state. The commission has the authority to acquire land and should select sites best suited for the purpose. It must report to the governor after ninety days of appointment, but the time can be extended if necessary.

MARYLAND

Institute of Alcoholism.—The National Committee on Alcohol Hygiene, in conjunction with a Baltimore sponsoring committee, will hold an institute on alcoholism in Baltimore, September 14. Three group sessions will be devoted to "The Effects of Alcohol on the Individual" by Dr. Robert V. Seliger, Baltimore; "New Approaches to Understanding the Alcoholic" by Victoria Granford, psychotherapist, Catonsville, Wilson Shaffer, Ph.D., Baltimore, and Dr. Lawrence F. Woolley, Towson, and "Alcoholism and Crime" by Robert M. Lindner, Ph.D., U. S. Public Health Service. At an evening session the speakers will be Dr. Seliger on "Alcoholics Are Sick People"; Lawrence Kolb, assistant surgeon general, U. S. Public Health Service, "Alcoholism as Viewed by the U. S. Public Health Service," and Dr. Haven Emerson, New York, "Alcoholism and Public Health."

MICHIGAN

Course on Postwar Diseases.—The University of Michigan School of Public Health, Ann Arbor, will conduct a course on postwar diseases for public health workers in the Middle West, September 20-22. On the first day virus diseases, particularly influenza and poliomyelitis, will be discussed by Dr. Thomas Francis Jr., University of Michigan Medical School, Ann Arbor, and director of the commission on influenza, U. S. Army; Dr. Don W. Gudakunst, New York, medical director of the National Foundation for Infantile

Paralysis; Major Albert B. Sabin, M. C.; Dr. John R. Paul, Yale University School of Medicine, New Haven, Conn., and Dr. Franklin H. Top, medical director of Herman Kiefer Hospital, Detroit. Exotic and tropical diseases will be discussed during the next two days by Brig. Gen. Leon A. Fox, field director of the U. S. Typhus Commission. Malaria will be discussed by Comdr. Lowell T. Coggeshall (MC) and Major Stanley B. Freeborn, M. C., and dysentery by Albert V. Hardy, surgeon, U. S. Public Health Service, and Dr. George D. Cummings, Lansing. Other speakers will include Dr. Joseph G. Molner, deputy health commissioner of Detroit, who recently returned from Mexico and Central America, on tropical diseases and Dr. Haven Emerson, New York, chairman of the committee on communicable diseases of the American Public Health Association, who will give a preliminary report on the activities of this group.

Fluorine Program in Michigan.—Grand Rapids has been chosen for a carefully controlled experiment in dental caries under the auspices of the Michigan Department of Health, U. S. Public Health Service and the University of Michigan School of Dentistry. The experiment will include the addition of 1 part per million of sodium fluoride to a municipal water supply artificially to determine whether a reduction can be made in dental caries. A careful clinical and bacterial examination of the saliva of Grand Rapids school children will first be made to establish a base line before the fluorine is put in the water. According to Dr. William DeKleine, state health commissioner, it is now generally accepted that the number of *Lactobacillus acidophilus* organisms found in the saliva is also an accurate diagnostic index of the activity of dental caries in that mouth. Areas having fluorine naturally in the municipal water have a much lower bacterial count. This study stems from the belief that mottled enamel occurring in certain areas of the country is caused by fluorine in the drinking water and causes the mottling only when the crowns of teeth are forming. Investigation showed much less dental caries in these areas than where there is no fluorine or only a trace in the drinking water. Further studies showed that in areas having from 0.5 to 1 part per million of fluorine in the municipal water supply there was a 50 to 60 per cent reduction in dental caries and yet this amount was not sufficient to cause disfiguring enamel. Studies have been carried out in various sections of the country. The plan to add the fluorine to the Grand Rapids water supply was approved by the city commission on July 31. The city was selected because it has a stable population, an item to be considered in an experiment to be continued over a number of years.

MONTANA

State Medical Election and Meeting.—Dr. Sidney A. Cooney, Helena, was named president-elect of the Medical Association of Montana at its annual meeting, July 14, in Butte, and Dr. James C. Shields, Butte, was inducted into the presidency. Dr. Raymond F. Peterson, Butte, is secretary. The following speakers were included on the program:

Dr. Harry L. Baum, Denver, Foreign Bodies in Air and Food Passages.
Dr. John K. Colman, Butte, Exogenic Bone Infections.
Dr. Henry E. Michelson, Minneapolis, Common Diseases of the Skin.
Dr. John M. Waugh, Rochester, Minn., Traumatic Injuries of the Abdomen.
Dr. Orville M. Moore Jr., Helena, Exanthema Subitum and Erythema Infectiosum.
Dr. Elma M. Howard, Miles City, Erythroblastosis.
Dr. Coran L. Bourdeau, Missoula, Surgical Indication in Gastric Lesions.
Dr. Chester W. Lawson, Glasgow, Experiences in China.
Dr. Earl L. Hall, Great Falls (subject not announced).

NEBRASKA

Dean Poynter Honored.—On July 15 the faculty and alumni of the University of Nebraska College of Medicine, Omaha, gave a dinner in honor of Dr. Charles William M. Poynter, dean of the medical school, in recognition of his seventieth birthday. Col. Edgar V. Allen, M. C., medical consultant of the Seventh Service Command, a graduate of the Nebraska medical school in 1925, was the toastmaster.

NEVADA

Mines Hospital Closed.—On August 15 the Tonopah Mines Hospital, Tonopah, was closed and the buildings and equipment merged into the Nye County Hospital. The action was taken after the closing of all gold and silver mines as nonessential war industries and the resignation of Dr. Robert R. Craig, medical director of the hospital for more than twenty-five years. Dr. Joseph H. Coogan, recently appointed county physician and health officer, will be in charge of the newly reorganized Nye County Hospital.

NEW JERSEY

Narcotic Violation.—Dr. Joseph L. Polizzotti, Paterson, pleaded guilty in the U. S. District Court at Trenton July 14 to a violation of the federal narcotic laws and paid a fine of \$500.

Illegal Practitioner's Fine Increased.—On August 11 the state supreme court ordered the first district court of Jersey City to amend a judgment fining George H. Coleman \$200 on a charge of practicing medicine without a license in Kearny by increasing the fine to \$500. The supreme court's action resulted from an appeal by the state board of medical examiners, which filed the original charge against Coleman and contended that the higher fine should have been imposed because the offense was his second, according to the *New York Times*.

NEW MEXICO

Personal.—Judson D. Dowling, senior surgeon of the United States Public Health Service Reserve, has been assigned to the New Mexico Department of Public Health as assistant state director of health.

New Mexico Joins Rocky Mountain Medical Journal.—Arrangements have been completed by which the *Rocky Mountain Medical Journal* will be the official journal of the New Mexico Medical Society. Dr. Carl H. Gellenthien, Valmora, is to be the editor for New Mexico.

State Medical Election.—Dr. Charles A. Miller, Las Cruces, was named president-elect and Dr. Carl H. Gellenthien, Valmora, was installed as president of the New Mexico Medical Society at its annual meeting recently. Dr. Leo B. Cohenour, Albuquerque, is secretary. The next annual meeting will be held in Santa Fe some time in June 1945.

NEW YORK

Poliomyelitis Delays Opening of Schools.—Opening of Hornell public schools, originally scheduled for September 5, has been postponed until October because of the infantile paralysis epidemic, the *Rochester Times-Union* reported August 22. At the time of the report Rochester had 39 patients under treatment, 21 of whom were city residents.

Special Lectures.—Dr. Orren D. Chapman, professor of bacteriology and parasitology, Syracuse University College of Medicine, Syracuse, addressed the St. Lawrence County Medical Society, August 17, in Gouverneur on "Tropical Diseases." Dr. Paul C. Clark, assistant professor of clinical medicine at Syracuse, addressed the Madison County Medical Society at Sylvan Beach, August 10, on "Penicillin Therapy." Both lectures were part of a cooperative project between the state medical society and the state department of health.

New York City

Dr. Lasersohn Named Assistant to President at Winthrop.—Dr. Martin Lasersohn, medical director of the Winthrop Chemical Company, has been appointed assistant to the president and assistant treasurer of the company. He has also been elected secretary of Fairchild Brothers and Foster, a Winthrop subsidiary. Dr. Lasersohn has been associated with the company since 1930.

Sentenced as Abortionist.—Dr. Stephen A. Leslie was sentenced July 18 in General Sessions to a one year term in the penitentiary as an abortionist, the *New York Times* reported. It was stated that Judge George L. Donnellan had denounced him as a refugee who had abused the privileges extended to him in America by operating an abortion mill at 993 Park Avenue for several years.

Ivan Hall Named Professor of Bacteriology.—Ivan C. Hall, Ph.D., since 1942 director of the central laboratory, contaminated wound project, subcommittee of surgical infections, National Research Council, formerly professor and head of the department of bacteriology and public health in the University of Colorado School of Medicine, Denver, has been appointed professor and chairman of the department of bacteriology at the New York Medical College, Flower and Fifth Avenue Hospitals. He will succeed Laura Florence, Ph.D., who will retire in September.

Personal.—Thomas P. Fleming, M.S., librarian of the Columbia University College of Physicians and Surgeons, has been appointed assistant director of the libraries of the university.—Dr. George T. Pack was recently decorated by the president of Chile with the title of Grand Officer of the Order of Merit.—Frank S. Lloyd, Washington, D. C., executive officer of the Committee on Physical Fitness of the Federal Security Agency, has been appointed chairman of the depart-

ment of hygiene of the College of the City of New York, succeeding Frederic A. Woll, Ph.D., who retired on account of age on August 31.

NORTH DAKOTA

New Director of Maternal and Child Hygiene.—Dr. Frederick G. Gunlaugson, Fergus Falls, Minn., has been appointed director of maternal and child hygiene of the North Dakota State Department of Public Health, succeeding Dr. Mary E. Soules, Dickinson, who resigned. Dr. Gunlaugson graduated at the University of Minnesota Medical School, Minneapolis, in 1935 and received his master of public health degree from Johns Hopkins.

Free Plasma for the Public.—The state legislature recently appropriated a fund to set up and finance a free plasma service under the direction of the director of the division of laboratories of the state department of public health in cooperation with the University of North Dakota, Grand Forks. Donor clinics are to be set up throughout the state with a mobile unit from the health department conducting clinics in each community. All donors are given a blood donor certificate indicating that its possessor has rendered a public service in the state by giving blood. Complete coverage of the state with normal supplies is the first objective of the program. Each package sent out into the state will contain one bottle of dried pooled normal human plasma, one bottle of 0.1 per cent citric acid solution for restoration of the plasma, a complete set of equipment for administering plasma, and directions for its use. The service is available free of charge to every one in the state.

OHIO

New Chairman of Anatomy.—Ralph A. Knouff, Ph.D., professor of anatomy at the Ohio State University College of Medicine, Columbus, since 1932, has been appointed chairman of the department.

License Suspended.—The license to practice medicine in Ohio of Dr. Ward C. Bell, formerly of Cleveland, has been suspended indefinitely. Dr. Bell was convicted of criminal abortion and served an indeterminate sentence in the Ohio Penitentiary, it is reported.

Physicians Honored.—The Portage County Medical Society gave a dinner recently in honor of two of its members, Drs. Lucius W. Prichard, Ravenna, and Joseph H. Krape, Kent. Dr. Prichard has completed fifty-four years of practice in Ravenna and Dr. Krape fifty years at Kent. Dr. Bernard H. Nichols, Ravenna, was toastmaster at the dinner.

Memorial for World War Physicians.—The Toledo Academy of Medicine has recommended the construction of a memorial building as a testimonial to the physicians of Toledo who served with the armed forces of the United States in World Wars I and II. The *Journal of the Michigan State Medical Society* reports that an assessment of \$300 per member for a new memorial building or \$150 per member for remodeling the present home of the academy of medicine is being presented to the membership for decision.

SOUTH DAKOTA

Sioux Falls Health Officer Goes to California.—Dr. Francis H. Redewill Jr. has resigned as director of the Sioux Falls health department to accept a position as venereal disease control officer of the Los Angeles County Health Department. He will be succeeded by Dr. Emil G. Ericksen, who once was health officer of Sioux Falls and who for the last year has been assistant to Dr. Redewill, according to the *Journal-Lancet*.

TENNESSEE

The Haggard Lecture.—Dr. Alfred Blalock, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, and formerly professor of surgery at Vanderbilt University School of Medicine, Nashville, recently delivered the annual Haggard Memorial Lecture at Vanderbilt on "Recent Advances in Surgery."

Walter Garrey Made Professor Emeritus.—Dr. Walter E. Garrey, professor and head of the department of physiology, Vanderbilt University School of Medicine, Nashville, retired June 30 with the title professor emeritus. According to an announcement from Dr. Waller S. Leathers, dean of the medical school, July 31, Dr. Garrey's successor had not yet been selected.

Personal.—Marion Murphy Brooke, Sc.D., associate in parasitology at the School of Hygiene and Public Health of the Johns Hopkins University, Baltimore, has been appointed

associate professor of preventive medicine at the University of Tennessee College of Medicine, Memphis.—Dr. James K. P. Blackburn, Pulaski, has been named a member of the state basic science board, succeeding Dr. Waller S. Leathers, Nashville, who resigned recently.

WEST VIRGINIA

State Meeting in Clarksburg.—The seventy-eighth annual meeting of the West Virginia State Medical Association will be held at Clarksburg, May 14-15, 1945. The Waldo, Stone-wall Jackson and Gore have been designated the convention hotels. Technical and scientific sessions will be held at the Waldo Hotel.

Educational Consultant in Cancer Control.—Mrs. Marian Patrick Hart, assistant chief of the division of social service in the state department of public assistance, Charleston, has been appointed educational consultant in the state division of cancer control, effective September 1. The appointment is a part of the expanded program of cancer control financed by the state legislature and recently inaugurated with the appointment of Dr. Paul R. Gerhardt as director (*THE JOURNAL*, March 4, p. 660).

Poliomyelitis Quarantine Modified.—To permit poliomyelitis patients to receive early treatment in hospitals suitably equipped, Dr. John E. Offner, Weston, state health commissioner, has modified the regulation requiring three weeks' quarantine to permit the immediate transfer of patients from their homes to a hospital. The order will continue in force until November 1. Written permission must be obtained from the local health officer or state health department before a patient may be moved from one county to another. Thirty-eight cases of poliomyelitis were reported to the state department of health from July 1 to August 16.

WYOMING

George Baker Named Acting Secretary of State Society.—Dr. George E. Baker, Casper, has been appointed acting secretary of the Wyoming State Medical Society during the illness of Dr. Marshall C. Keith, secretary. Dr. Keith was taken ill July 1 and will not be able to resume his activities for a while.

GENERAL

College of Surgeons Cancels Meeting.—The American College of Surgeons, on action of its board of regents, has canceled its annual clinical congress because of the acute war situation that has developed, involving greater demands than at any time in the past on our transportation systems for the carrying of wounded military personnel, troops and war material. The congress was to have been held in Chicago, October 24-27.

Meeting of Obstetricians, Gynecologists and Abdominal Surgeons.—The fifty-sixth annual session of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons will be held at the Homestead, Hot Springs, Va., under the presidency of Dr. Willard R. Cooke, Galveston, Texas (*THE JOURNAL*, August 12, p. 1051). Features of the meeting will include a series of motion pictures and a banquet address by Hon. Dave E. Satterfield Jr., member of Congress from Virginia. There will be a golf tournament on Saturday, September 9, at which the play will be for the President's Trophy, given in 1938 by Dr. Paul Titus, Pittsburgh, then president of the association. Dr. James R. Bloss, 418 Eleventh Street, Huntington, W. Va., is the secretary of the association.

Wisconsin Foundation Wins Court Reversal.—A United Press dispatch from San Francisco August 24 stated that the U. S. Circuit Court of Appeals the previous day had withdrawn an opinion handed down June 30, 1943 invalidating patents of the Wisconsin Alumni Research Foundation involving the treatment of rickets with vitamins. The court held at the time that vitamins, being derived from the sun, could not be patented, according to the *Chicago Daily News*. In contradiction of this opinion the foundation in August 1943 asked for a rehearing of the case, which charged a Los Angeles company with infringement of the patents, it was stated. No explanation was given for the withdrawal, which was said to be almost unprecedented in court procedure, the *News* reported.

Special Society Elections.—Dr. William H. Daniel, Los Angeles, was elected president of the American Proctologic Society at its annual meeting in Chicago. Dr. Joseph W. Ricketts, Indianapolis, vice president, and Dr. Harry E. Bacon, Philadelphia, secretary. The next annual meeting of the society will be held in New York preceding the annual

session of the American Medical Association.—Dr. Claude S. Beck, Cleveland, was chosen president of the American Association for Thoracic Surgery at its annual meeting in Chicago recently. Dr. Isaac A. Bigger, Richmond, Va., is vice president and Lieut. Col. Richard H. Meade Jr., M. C., Memphis, Tenn., secretary.—Dr. S. Judd Beach, Portland, Maine, was chosen president of the American Ophthalmological Society at its annual meeting in Hot Springs, Va., recently. Dr. Walter S. Atkinson, Watertown, N. Y., is secretary. The next annual meeting will be held in Hot Springs, Va., June 6-8, 1945.

New Group for Rheumatic Fever.—The Council on Rheumatic Fever has been formed to focus attention on the problem of rheumatic fever. Organizations comprising membership in the new council include the American Medical Association, American College of Physicians, American Rheumatism Association, American Academy of Pediatrics, American Public Health Association, American Hospital Association, American Association of Medical Social Workers, American Nurses Association and the American Heart Association. The establishment of the new group stemmed from action taken at a conference on rheumatic fever in New York, January 26-27, at which representatives from the various military services and nationally interested groups agreed that a concentrated program on rheumatic fever should be instituted. The American Heart Association, under whose authority the creation of the new group was placed, announces that a suggestion has been made to incorporate the council as an independent organization under the laws of New York state. It is hoped that a fund of \$50,000 will be obtained within the near future to justify the selection of a director, the rental of offices and the employment of an office staff. Currently about \$7,000 is available, while another \$5,000 is expected soon. Negotiations are in progress with officers of the American Legion in the hope that the Legion may accept the responsibility for the financial support of the council on a national scale.

Joint Meeting of Radiologists.—A joint meeting of the American Roentgen Ray Society and the Radiological Society of North America will be held at the Palmer House, Chicago, September 24-29, under the presidency of Drs. Sherwood Moore, St. Louis, and Eldwin R. Witwer, Detroit, respectively. Among the speakers will be:

Drs. Herman L. Kretschmer, President, American Medical Association, and Fay H. Squire, Chicago, A Study of the Ureters in Bladder Neck Obstructions.

Col. Byrl R. Kirklin, M. C., representing Surgeon General Norman T. Kirk of the Army (subject not announced).

Lieut. Comdr. Robert K. Arbuckle (MC), representing Surgeon General Ross T. McIntire of the Navy, Lieut. G. Hunter Shelden (MC) and Lieut. Robert H. Pudenz (MC), Pantopaque Myelography: Correlation of Roentgenological and Neurosurgical Findings.

Drs. Joseph George Teplick and Alison H. Price, Philadelphia, Progressive Bilateral Bulbourethral Ectopy.

Dr. John O. Turek, M. C., Robert O. Turek, M. C., Planigr. and in the Diagnosis of Cancer.

Dr. Robert Aspect of Tuberculous Calcific Study.

Dr. Arbo Alar Irradiation in Carcinoma of the Prostate.

Major Milton Friedman, M. C., and Lieut. Col. Lloyd G. Lewis, M. C., An Improved Technic for the Treatment of Carcinoma of the Testis.

Dr. Russell L. Haden, Cleveland, Hematological and Clinical Characteristics of Leukemias.

Drs. Ross Golden and Paul H. Ducharme, New York, X-Ray Demonstration of Cecal Deformity in Amebiasis.

Drs. Percival Bailey and Theodore J. Wachowski, Chicago, Roentgen Therapy for Brain Tumors.

Dr. William Gayle Crutchfield, University, Va., Neurosurgical Treatment of Patients with Advanced Malignant Disease.

Dr. Dallas B. Phemister, Chicago, Subcortical Cystlike Lesions of Joints.

Drs. Laurence L. Robbins and Clayton H. Hale, Boston, Roentgen Appearances in Collapse of the Lung and Its Subdivisions: Preliminary Report.

Drs. Howard B. Hunt and Donald H. Breit, Omaha, Postirradiation Cutaneous Necrosis: A Study of Its Mechanism, Course and Treatment.

Lieut. Henry L. Jaffe (MC), Evaluation of Roentgen Therapy for Filariasis.

Dr. Lawrence Reynolds, Detroit, will deliver the Caldwell-Carman Lecture on Tuesday.

Medical Section of A. A. A. S. Meeting.—Section N, the medical section of the American Association for the Advancement of Science, will hold a joint meeting September 12 with the American Society of Parasitologists and the American Society of Zoologists. The session will be held in the Academy of Medicine of Cleveland and will be devoted to a symposium on "Parasitology in Relation to the War." Another joint session of the section with the section on engineering (M) will be a symposium on "Aviation Medicine." On Thursday a joint session will be held with Alpha Epsilon Delta, national honorary premedical fraternity, on "Premedi-

cal Education." Among the speakers in the symposium on "Parasitology in Relation to the War" will be:

Brig. Gen. James S. Simmons, M. C., The Wartime Importance of Tropical Diseases.

Major Oliver R. McCoy, M. C., Malaria and the War.

Clay G. Huff, Sc.D., and Frederick Coulston, Ph.D., University of Chicago, The Development of Malarial Sporozoites in the Vertebrate Host.

Dr. Harold W. Brown, Columbia University College of Physicians and Surgeons, New York, Filariasis.

Dr. Rolla E. Dyer, National Institute of Health, Bethesda, Md., Typhus Fever.

Walter E. Dove, Sc.D., U. S. Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture, Washington, D. C., Development of Louse Powders for the Armed Forces.

Benjamin Schwartz, Ph.D., U. S. Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C., Parasites in Relation to Production of Meat and Other Animal Products in Wartime.

On Friday September 15 a symposium on science and the press, sponsored by the National Association of Science Writers, will be presented at the Hotel Statler by Louis B. Seltzer, editor of the *Cleveland Press*; Martin J. Porter, New York, editor of the *American Weekly*; George E. Penday, Pittsburgh, assistant to the president of Westinghouse Electric & Manufacturing Company, and Dr. Morris Fishbein, Editor of *THE JOURNAL*. Robert D. Potter, science editor of the *American Weekly* and president of the National Association of Science Writers, will preside and Dr. Anton J. Carlson, Chicago, president of the American Association for the Advancement of Science, will give the introductory remarks. These meetings will be held during the session of the A. A. S. in Cleveland, September 11-16.

CANADA

Personal.—Dr. Lorimer J. Austin, professor of surgery, Queen's University Faculty of Medicine, Kingston, Ontario, recently was presented with the Montreal medal "for meritorious contribution to the honour of Queen's." The medal is awarded occasionally by the Montreal alumni of the university.

Course in Tropical Medicine.—McGill University Faculty of Medicine, Montreal, Quebec, is offering for the first time a diploma course in tropical medicine. The course is also suggested as a refresher course for medical graduates who have been working in the tropics and who wish to take advanced work in parasitology and other branches of tropical medicine. The course is divided into three units: tropical medicine and parasitology, care of ambulatory patients and one in which facilities have been arranged for clinical experience in the tropics. Thomas W. M. Cameron, D.Sc., professor of parasitology at McGill, is in charge of the course.

LATIN AMERICA

Health Activities in Latin America.—*Medical Center.*—The Anglo-American Caribbean Medical Center was opened in July, Port-of-Spain, Trinidad. The establishment of the center is an initial step in the program fostered by the Anglo-American Caribbean Commission to raise health standards in the West Indies.

Committee to Control Sandfly.—Dr. Henry C. Dooling, chief health officer of the Panama Canal Health Department, has appointed a committee to devise a program for the relief and protection of residents from the sandfly (*Phlebotomus*). The sandfly is the carrier of numerous diseases, but in Panama it is known to transmit only the American cutaneous leishmaniasis. The committee is composed of a health officer, a sanitary engineer, a physician, an epidemiologist and an entomologist.

Personal.—Clarence H. Waring, medical director, U. S. Public Health Service, has recently succeeded Dr. Henry A. Holle as chief quarantine officer of the Panama Canal Health Department. Dr. Holle has left Panama for a new assignment in New York.—Dr. Fernando D. Gómez, Montevideo, was recently appointed rector of the Instituto de Tisiología of the Faculty of Medicine of Montevideo, succeeding Dr. Juan B. Morelli, who recently retired.—Dr. Juan A. Sánchez was recently appointed honorary member of the Asociación Médica Argentina.—Announcement is made of the first anniversary of the death of Dr. Nicolas A. Solano, which was commemorated in special services at Herrera Cemetery, Panama City, July 23. The observance was conducted by the National Liberal Party, of which the late physician was said to have been national chairman at one time.

CORRECTION

Spontaneous Rupture of Aorta.—In the article by Dr. Douglas Symmers entitled "Spontaneous Rupture of the Aorta in Syphilitic Aortitis with Aneurysm," in the August 12 issue, page 1035, the word "with" in the title should read "without."

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 29, 1944.

The Radical Reform of Medical Education

In October 1941 the minister of health announced the intention of the government to inquire into the organization of medical schools, particularly with regard to facilities for clinical teaching. A small committee consisting mainly of leading teachers was appointed. It examined witnesses representing all the medical schools and others interested in medical education, including such Americans in this country as Professor Cutler and Col. William S. Middleton. The result is an elaborate report of 300 pages, in which every aspect of the subject is discussed.

Properly planned and carefully conducted medical education is held to be the essential foundation of a comprehensive health service. The national policy should be to secure for every one the highest possible standard of physical and mental health, the report says. Physicians must bear much of the responsibility for attaining this goal, and graduate and postgraduate training must impart the necessary knowledge to physicians. The present system of medical education is held to be seriously deficient in this respect. To the neglect of the promotion of health, medical practice—and consequently medical education—has been concerned primarily with disease chiefly as it affects individuals. A radical reorientation of medical education and practice is essential, the committee believes. One of the basic proposals is that throughout undergraduate and postgraduate education emphasis must be placed on acquisition of a sound knowledge of all measures that may make and preserve a healthy nation.

Although the nation is justified in taking pride in the reputation of British medical practice and traditional methods of education, there is urgent need for improvements, it is held. The training of the undergraduate should provide a university education on broad and liberal lines. The essential unity of medicine should be observed throughout, and the teaching should be so organized that the whole course becomes a smooth and logical development. While primarily practical, the training should give a clear understanding of the constantly developing scientific basis of medicine. The main emphasis should be on fundamental principles rather than on the mass of purely factual knowledge, the committee states.

The unit of organization for undergraduate education should be a medical teaching center consisting of a university medical school and a group of teaching hospitals and clinics of the district health service. A new pattern of staffing is believed to be necessary; more whole time appointments and salaries for clinical teachers in consideration of well defined duties are proposed. A medical school admitting the optimum number, 100 students a year, should have access to between 950 and 1,000 beds, roughly distributed as general medical 250, general surgical 250, maternity 100, gynecologic 50, children 100, and special departments and beds for special purposes 200 to 250. Major teaching hospitals should be linked by means of their staffs with outlying hospitals, and medical schools, as partners in the national health service, should have a place in the administration of the service. Preclinical scientific subjects should be taught by full time professors and there should be more junior staff members, it is suggested. In the clinical field there should be more full time appointments in all grades. At the earliest possible date every medical school should have a whole time professor in medicine, surgery and obstetrics and gynecology, according to the report.

STUDENTS

The only barrier to admission to a medical school should be unsuitability. Financial assistance should be given to medical students so that young people of ability are not deterred from entering the medical profession. Students should not be selected on the basis of examinations alone. Interviews are essential, and the possible development of aptitude tests is envisaged by the committee. There should be coeducation in all schools, and all hospital appointments should be filled by open competition, without any sex barrier. It is estimated that the places provided for women students should amount to about one fifth of the whole number.

CLINICAL INSTRUCTION

An introductory clinical course of planned scientific instruction, extending over not less than four months, is the best means of effecting a smooth transition from preclinical to clinical study, the report states. A medical student needs a coherently unified knowledge of medicine, which he has to acquire in an atmosphere of specialization and from teachers who, to an increasing extent, will be specialists. The teaching should be organized in five divisions: preclinical studies, pathology, medicine, surgery, obstetrics and gynecology. Under medicine should be included child health, psychiatry and social medicine. Clinical instruction should be continuous throughout the year, with emphasis on basic principles. Special attention should be paid to minor ailments and less to the technical details of surgical operations, the committee feels. There is need for more instruction in social medicine, child health and psychology. The total course up to the final examination should last four and one-half years. After passing, the student should have a junior resident's appointment for twelve months in one or more approved hospitals before admission to the medical register.

POSTGRADUATE EDUCATION

Postgraduate study should be a regular feature of general practice, it is claimed. The provision of periodic intensive refresher courses should be regarded as only a short term expedient. A better policy, according to the committee, is to bring general practitioners, by such means as clinical assistantships, into regular association with the work of hospitals and specialists. For specialists a minimum of four or five years' training after registration is proposed, and trainees should hold salaried appointments at teaching centers or special hospitals. As adequate training in tropical medicine cannot be obtained in this country, it is suggested that; having obtained his theoretical and laboratory instruction here, the student should hold an approved hospital appointment in a tropical country.

Industrial Rehabilitation Center Established by the Ministry of Labor

Much increased attention is now being given to rehabilitation. The Ministry of Labor has opened a center near London for industrial rehabilitation of male patients. It is realized that the complete use of available manpower, so essential for total war, demands the complete utilization of the individual worker. The center follows lines evolved by the army to meet this problem. It is equipped with workshops for various building and engineering occupations, and there are courses for handy men and gardeners, all under a highly qualified teacher. These facilities are used to test suitability for various occupations. The medical officer, who has undergone a course of special instruction, discusses with the manager the aptitude and potential capacity of each man, cooperates with him in the choice of employment and regulates progression of training on medical grounds. He has a staff of medical auxiliaries, including physical therapists. The remedial gymnastics are directed by a senior sergeant instructor of the Army Physical Training Corps, released for the purpose from a military convalescent depot.

Provision is made for entertainment, and particular attention is paid to the proper use of leisure.

The course is of six to eight weeks duration and is active in character. It is therefore not suitable for men in the earlier convalescent stages. On completing the course the men go either directly to employment in a previously held or some other occupation or are transferred to a vocational training center for a course in the new occupation chosen for them. The disabled man is in need of guidance in the choice of his future career, for his previous occupation may have been unsuitable for him. He requires the advice of a physician versed in the many sided aspects of rehabilitation and of an expert conversant with the demands of different industries. The man may regard his disability as the end of all his hope and, left to himself, may drift into unsuitable employment. The psychologic factor is therefore important, and the atmosphere and expert advice of the center are directed toward restoring confidence.

Profits of Proprietary Pills

At the sixteenth ordinary general meeting of Beechams Pills, Limited, it was announced that profits for the year ended March 31 earned by the companies of the group operating in the British Empire and in almost all parts of the world other than Europe amounted to \$7,000,000, as compared with \$6,000,000 in the previous year. The overseas trade was most satisfactory, the announcement said, and provides encouraging hope for the postwar period. The business commenced over one hundred years ago with the sale of the proprietary pill which gives its name to the company. During the past four years much time has been devoted to the development of overseas trade, it was stated.

PALESTINE

(From Our Special Correspondent)

TEL AVIV, July 14, 1944.

Epidemic of Louse Borne Typhus at the Dead Sea

In November 1943 an epidemic of louse borne typhus broke out among workers employed by the Palestine Potash Ltd. (Arabs from Hedjaz, Transjordan and neighboring countries). Following a positive Weil-Felix reaction in the first 2 cases, all suspected persons were sent to the hospital. All those who had been in contact with them were vaccinated, their personal effects were burned and the whole camp was disinfected. The energetic measures taken by Kupat Holim (the Workers' Sick Fund of the General Federation of Jewish Labor in Palestine), in cooperation with the Hebrew University and the government of Palestine, proved successful. In all, 10 persons occupying tents in the vicinity of the first victims contracted the disease. The last case occurred on Dec. 20, 1943. All the patients were in an undernourished condition and their standards of hygiene were at a low level. Two of the patients died.

Allergy in Palestine

Dr. I. Gutman of Jerusalem gives a survey of the condition of allergy in Palestine in the *Palestine and Near East Medical Journal* of December 1943 as follows:

About 3 per cent of the Jewish population of Palestine suffer from allergic diseases (major allergy), a figure far short of 10 per cent of the number submitted by American authors for America and somewhat lower than in Europe. In the Arab section of the population as well allergic diseases are of widespread occurrence. The most impressive factor which distinguishes Palestinian from European observations is the high proportion of susceptible children; the percentage in the pre-school age group in Palestine is more than twice as high as in Europe.

The distribution of allergic diseases in the various organs shows that bronchial asthma and vasomotor rhinitis account alike here and in Europe for more than 50 per cent of all

allergic patients. The main causative factors are "climate allergens," i. e. molds and fungi, in the humid warm atmosphere of the coastal regions. Skin diseases amount to about 25 per cent, excluding scrofula of infants. Allergic intestinal disturbances appear twice as often as in Europe, even without the colitis. This number is certainly still higher, considering that there are about three times as many sufferers from colitis in Palestine as from asthma. Hay fever appears less frequently, but then this illness is still little known here. Conjunctivitis vernalis (spring catarrh) is often encountered.

Extension of Hospital Accommodation in Haifa

Palestine has for many years suffered from a severe shortage of hospital accommodation, particularly in the Haifa district.

For every thousand persons in the Jewish section of the population of the country the available bed strength in the various districts of the country is as follows:

	Beds
In Jerusalem and vicinity.....	5.1
In Tel Aviv and the south of Palestine.....	1.4
In Haifa and vicinity	0.9
In the plain of Esdraelon and Galilee.....	2.7

Haifa is a port town and the center of heavy industry, as well as the gathering place of large numbers of new immigrants. The hospital which serves the Jewish community of Haifa has only small departments for surgery, maternity and children. For Haifa and its vicinity, which has a Jewish population of over 70,000, not a single hospital bed is available for internal diseases. In view of this situation the Kupat Holim (Sick Fund of the General Federation of Jewish Labor in Palestine) felt bound to purchase a building and adapt it as a small hospital, containing 40 beds. The cost of this building, with its renovation and equipment, will amount to \$125,000. Most of the beds will be devoted to cases of internal diseases. In accordance with an agreement arrived at with the Jewish Community Council of Haifa, it will admit Haifa residents even though they may not be members of Kupat Holim.

Medical Aid to the Red Army

The executive committee of the General Federation of Jewish Labor in Palestine, through its representative in London, has presented to the Russian ambassador, Mr. Maisky, the sum of £P 10,000 for the purchase of two fully equipped ambulances for the Red Army. At present a new shipment is being prepared of medically equipped field boxes, which, as the Soviet medical institutions have requested, contain medical instruments and materials for the use of doctors at the front. The nearer the Red armies approach the great day of victory, the more efficient becomes the service of the doctor who is equipped with a field box containing all the required appliances and instruments to render first aid to the wounded soldiers on the front.

Marriages

JOE LEE FRANK JR., Richmond, Va., to Miss Barbara Olive Bloxam of Roxboro, N. C., in Fayetteville, N. C., July 14.

EDWARD ARTHUR SHORTEN, Youngstown, Ohio, to Miss Mary Virginia Williams of Albion, Ill., July 8.

JOHN KELLER GRIFFITH JR., Slidell, La., to Miss Elizabeth Theriot of Gueydon in New Orleans, July 6.

WILLIAM E. SANDERS, Long Beach, Calif., to Miss Blanche Calvert of Des Moines in Pasadena, July 16.

ARTHUR SELDON MANN, Alton, Ill., to Lieut. Mildred Wiles of Seattle in England, July 14.

JOHN C. GLENN JR., Durham, N. C., to Miss Mary Eliza Ezzell of Rose Hill, July 7.

JAMES R. DWYER, Renovo, Pa., to Miss Anne Norton of Baltimore, July 24.

JOHN P. CREWS, Inverness, Miss., to Miss Nancy Curry in Knoxville, July 4.

Deaths

Willis Elliott Bowen * Rochester, N. Y.; Cornell University Medical College, New York, 1902; also a pharmacist; past president of the Rochester Academy of Medicine; member of the Rochester Hospital Council, Inc., and the Rochester Hospital Service Corporation; fellow of the American College of Surgeons; served during World War I; formerly on the staff of the Rochester City Hospital, now known as the Rochester General Hospital; a founder, one of the original board of directors, which he had served as president since March 1934, member of its executive committee and formerly chief of the surgical staff, Park Avenue Hospital, where he died July 11, aged 72, of Parkinson's disease, gallstones and diabetes mellitus.

Robert Lee Russell, Weaverville, N. C.; Columbian University Medical Department, Washington, D. C., 1901; joined the U. S. Indian Service, serving as agency and field physician at Rosebud, S. D., as agency physician at Anadarko, Okla., and as superintendent of the Sac and Fox Sanatorium, Toledo, Iowa; later chief of health in the Indian Service, stationed at Washington, D. C.; transferred to the Veterans Administration in 1920, from which he retired in 1940; formerly chief of the tuberculosis and general medical service at the Veterans Administration Facility in Oteen; served on the staffs of the U. S. Veterans hospitals in Fort Bayard, N. M., and Fort Lyon, Colo.; died in Asheville June 28, aged 73.

Richard Fenner Yarborough, Louisburg, N. C.; Columbian University Medical Department, Washington, D. C., 1898; honorary member of the Medical Society of the State of North Carolina; past president and secretary of the Franklin County Medical Society; a captain in the medical corps of the U. S. Army during World War I; formerly physician to the North Carolina State College for Agriculture and Engineering and member of the board of directors of the State Hospital in Raleigh; served as a member of the board of health of Franklin County and as county health officer; died June 22, aged 72, of coronary occlusion.

Percy Daniel Moulton * Colonel, U. S. Army, retired, Los Angeles; Jefferson Medical College of Philadelphia, 1907; graduated from the School for Flight Surgeons in 1921 and the Air Service Primary Flying School in 1925; served during World War I; entered the medical corps of the U. S. Army as a captain on Sept. 14, 1920 and later promoted to major, lieutenant colonel and colonel; retired Dec. 31, 1939; at one time instructor in pediatrics at his alma mater and on the staff of the Jefferson Hospital, Philadelphia; died in the Hoff General Hospital, Santa Barbara, Calif., Dec. 24, 1942, aged 61, of myocardial infarction.

William J. Blackburn * Dayton, Ohio; Pulte Medical College, Homeopathic, Cincinnati, 1900; University of Michigan Homeopathic Medical School, Ann Arbor, 1915; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Ohio State Homeopathic Medical Society, Southern Homeopathic Medical Society and the Dayton Ophthalmological and Laryngological Society; fellow of the American College of Surgeons; for many years a member of the staff and of the board of trustees of Miami Valley Hospital and a lecturer at the hospital's school of nursing; died July 16, aged 75.

John Joseph Sweeney, Doylestown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1911; member of the Medical Society of the State of Pennsylvania; served overseas during World War I in the medical corps of the U. S. Army and was honorably discharged with the rank of major; for many years Bucks County coroner; chief Burgess of Doylestown; president of the city board of health; past president of the Kiwanis Club of Doylestown and president of the Second World War Memorial Committee; physician at the Bucks County Prison; died June 27, aged 57.

Leonard Francis Logiodice, Belchertown, Mass.; College of Physicians and Surgeons, Boston, 1920; member of the American Association on Mental Deficiency; served on the staffs of the Grafton State Hospital, North Grafton, and the Boston Psychopathic Hospital; received by the Pope in 1933; awarded two certificates of appreciation from the President for services rendered in the administration of the Selective Service System, local board number 34, Massachusetts; assistant physician on the staff of the Belchertown State School; died August 1, aged 56.

Frank Newton Wells, Pittsfield, Ill.; Chicago Homeopathic Medical College, 1895; member of the Illinois State Medical Society; served during World War I; lieutenant colonel in the medical reserve corps, not on active duty; past president and secretary of the Pike-Calhoun Counties Medical Society; at one time president of the school board of Cortland and Kirkland, Ill.; served as alderman and mayor of Pittsfield; for many years city and county physician; honorary member of the staff of the Illini Community Hospital; died June 27, aged 75.

Roy Wood Adkins, Fort Lauderdale, Fla.; Starling-Ohio Medical College, Columbus, 1911; member of the Ohio State Medical Association; died May 27, aged 57, of coronary heart disease.

Elias Marion Akins, Etowah, Tenn.; Chattanooga Medical College, 1903; died in Asheville, N. C., June 22, aged 70, of pulmonary tuberculosis.

James Ulysses Allen, Benton Harbor, Mich.; Rush Medical College, Chicago, 1923; member of the Michigan State Medical Society; served with Hospital Corps, 370th Infantry, American Expeditionary Forces, during World War I; served on the staff of St. Joseph Sanitarium, St. Joseph, and on the courtesy staff of the Mercy Hospital; died in the Provident Hospital, Chicago, July 4, aged 52, of cardiorenal disease.

Elsworth Frederick Arble, Carrolltown, Pa.; Baltimore Medical College, 1898; member of the Medical Society of the State of Pennsylvania; at one time first vice president of the Cambria County Medical Society; formerly a member of the board of health of Carrolltown and the school board; served during World War I; an organizer, former president of the board and staff member of the Miners' Hospital, Spangler, where he died July 5, aged 71, of hypertensive heart disease.

Wesley Lewis Boyden, Brillion, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; served overseas with the Thirty-Second Division, 127th Infantry Medical Unit, during World War I; for many years city physician of Brillion; formerly chief of staff, St. Mary's Hospital, Green Bay, where he died June 26, aged 56, of acute myocarditis and acute cholecystitis.

Arthur Mario Brianza, Chicago; College of Physicians and Surgeons of Chicago, 1892; at one time member of the city board of health; formerly on the staff of the Cook County Hospital; died at his home in Oak Park, Ill., July 11, aged 76, of angina pectoris.

Alfred William Brinham, Windber, Pa.; College of Physicians and Surgeons, Baltimore, 1905; member of the Medical Society of the State of Pennsylvania; for many years member of the board of health of Scalp Level; served as vice president of the Scalp Level Merchants and Miners Bank until it merged with the Windber Trust Company; died June 22, aged 63, of acute nephritis.

Elias Harry Brubaker * Flora, Ind.; Medical College of Indiana, Indianapolis, 1905; past president and secretary of the Carroll County Medical Society; died in the Home Hospital, Lafayette, June 28, aged 63, of a ruptured bladder following a prostatectomy.

John Thomas Burns * Kalamazoo, Mich.; University of Michigan Medical School, Ann Arbor, 1917; served overseas during World War I; on the staff of the Borgess and Bronson hospitals; died at his summer home in Gull Lake June 25, aged 55, of coronary disease.

David Clark Cather * Medical Director, Rear Admiral, U. S. Navy, retired, Herndon, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; commissioned a lieutenant (jg) in the medical corps of the U. S. Navy on June 9, 1904; later a lieutenant, lieutenant commander, commander, captain and rear admiral; retired Dec. 1, 1942 for incapacity incident to service; fellow of the American College of Surgeons; died in the U. S. Naval Hospital, Corona, Calif., June 25, aged 64, of pulmonary tuberculosis.

John Edward Curtis * Lemmon, S. D.; University of Louisville (Ky.) Medical Department, 1909; superintendent of the Perkins County Board of Health; president of the South Dakota State Public Health Association; died in an Aberdeen hospital May 6, aged 68, of coronary occlusion.

Floren Fred Davis, Clayton, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the Illinois State Medical Society; died June 21, aged 64, of coronary heart disease.

Wirt Adams Duvall, Baltimore; University of Maryland School of Medicine, Baltimore, 1888; formerly chief surgeon

of the state police department and member of the state board of education; died June 17, aged 80, of chronic nephritis, arteriosclerosis and coronary occlusion.

William T. Easley, Houston, Texas; St. Louis College of Physicians and Surgeons, 1883; member of the Illinois State Medical Society and its "Fifty Year Club"; served as president, secretary and treasurer of the Bond County (Ill.) Medical Society; served as second lieutenant in the Fourth Regiment, Company F, Illinois National Guard, when the militia was active in Greenville; formerly coroner of Bond County; at one time member of the board of education in Greenville, Ill.; died June 20, aged 86, of hypostatic pneumonia following a fall.

Eli A. Fisher @ Yorkshire, Ohio; Medical College of Ohio, Cincinnati, 1888; past president of the Darke County Medical Society; died in the Wayne Hospital, Greenville, June 28, aged 80, of carcinoma of the stomach.

Samuel Watson Fox, Breton Woods, N. J.; Jefferson Medical College of Philadelphia, 1910; died June 22, aged 66, of cirrhosis of the liver.

Frank Joseph Gallagher, Tucson, Ariz.; University of Wooster Medical Department, Cleveland, 1912; fellow of the American College of Surgeons; served in the medical corps of the U. S. Army during World War I; served on the staffs of St. John's, St. Ann's Maternity and St. Alexis hospitals in Cleveland and St. Mary's Hospital; died June 22, aged 55, of pulmonary tuberculosis.

Pietro Giacchella, Altoona, Pa.; Regia Università di Torino Facoltà di Medicina e Chirurgia, Italy, 1896; one of the founders and member of the staff of the Mercy Hospital; died June 28, aged 79, of cerebral hemorrhage.

Edward Winchester Goodenough, Waterbury, Conn.; Yale University School of Medicine, New Haven, 1893; for many years clinical assistant in pediatrics at his alma mater; member of the Connecticut State Medical Society; formerly commissioner of education in Waterbury, medical inspector of schools, city supervisor and milk and food inspector; served on the staff of the Waterbury Hospital; died in the Masonic Home, Wallingford, July 10, aged 78.

Haynie Melvin Grace @ Chillicothe, Mo.; Missouri Medical College, St. Louis, 1891; a member of the chamber of commerce; formerly physician and surgeon to the State Industrial Home for Girls; died in the Major Clinic, Kansas City, June 13, aged 78, of cerebral thrombosis.

John Morton Greene, Falls City, Neb.; University of Louisville (Ky.) Medical Department, 1902; member of the Nebraska State Medical Association; served as president of the Richardson County Medical Society; on the staff of Our Lady of Perpetual Help Hospital; division surgeon for the Missouri Pacific Railroad; died June 10, aged 69, of coronary thrombosis.

Charles Wesley Hall, Mount Vernon, Ill.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; University and Bellevue Hospital Medical College, New York, 1901; member of the Illinois State Medical Society; served as president of the Southern Illinois Medical Society; a major in the medical corps of the U. S. Army and in charge of an evacuation hospital in France during World War I; died June 21, aged 63, of coronary occlusion.

Helen Willard Ham, Middleboro, Mass.; Tufts College Medical School, Boston, 1906; died April 30, aged 69.

Arthur Graham Harris, Fairfield, N. C.; University of the South Medical Department, Sewanee, Tenn., 1905; died in the Riverside Hospital, Newport News, Va., June 28, aged 67, of cirrhosis of the liver and arteriosclerosis.

Pleasant L. Henderson, Morristown, Tenn.; Bellevue Hospital Medical College, New York, 1896; member of the Tennessee State Medical Association; died June 18, aged 78, of complications attributed to injuries received in an automobile accident.

Edward Herbert @ Fall River, Mass.; Columbia University College of Physicians and Surgeons, New York, 1902; formerly district physician for the city of Fall River; died in a local hospital June 26, aged 69, of diabetes mellitus.

Stewart Felteau Hill, Macon, Miss.; University of Alabama School of Medicine, 1912; served during World War I; member of the board of aldermen of Macon; died June 14, aged 57, of carcinoma of the right lung.

Charles Edwin Homan Jr., New Orleans; Johns Hopkins University School of Medicine, Baltimore, 1923; member of the Louisiana State Medical Society; fellow of the American College of Physicians; formerly practiced in Chattanooga, Tenn.; at one time assistant medical director of the Connec-

ticut Mutual Life Insurance Company, Hartford; since January 1943 medical director of the Ochsner Clinic; died July 25, aged 46, of coronary thrombosis.

Robert Pearson Hooper, Kosciusko, Miss.; Memphis (Tenn.) Hospital Medical College, 1913; member of the Mississippi State Medical Association; served during World War I; died in Durant May 20, aged 56.

Arthur West Hopper, Washington, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1909; member of the Medical Society of the State of Pennsylvania; medical director of Washington and Green counties; died in the Western Pennsylvania Hospital, Pittsburgh, June 20, aged 62, of acute myocardial failure.

Mathew Marshall Huling, Winchester, Tenn.; Tennessee Medical College, Knoxville, 1902; for many years chairman of the Republican executive committee of Franklin County; secretary of the Franklin County Election Commission; formerly postmaster of Winchester; killed June 14, aged 71, when the automobile in which he was driving was struck by a truck.

Logan M. Kifer, McKeesport, Pa.; Jefferson Medical College of Philadelphia, 1878; member of the Medical Society of the State of Pennsylvania; died June 8, aged 90, of heart disease.

Adolph Frederick Konther @ Brooklyn; Long Island College Hospital, Brooklyn, 1902; consulting physician, Lutheran Hospital; died June 19, aged 78, of coronary thrombosis.

Francis Ferdinand Kramer @ Cincinnati; Medical College of Ohio, Cincinnati, 1905; a lieutenant in the medical corps of the U. S. Army during World War I; on the staffs of St. Mary's and St. Francis hospitals; died June 14, aged 62, of diabetes mellitus.

Nelson Egbert Laidacker, China, Texas; Medical College of Indiana, Indianapolis, 1903; member of the State Medical Association of Texas; veteran of the Spanish-American War; died May 25, aged 75.

Jefferson Brown Latta, Fort Bayard, N. M.; Columbia University College of Physicians and Surgeons, New York, 1905; veteran of the Spanish-American War and World War I; formerly a surgeon in the U. S. Public Health Service reserve; served on the staffs of various U. S. Veterans hospitals; pathologist at the Veterans Administration Facility, where he died June 8, aged 63, of carcinoma of the liver.

John Russell Leadsworth, Anaheim, Calif.; College of Physicians and Surgeons of San Francisco, 1897; died in a hospital at Fullerton June 4, aged 78, of Parkinson's disease.

Bedford E. Love, Roxboro, N. C.; University of Maryland School of Medicine, Baltimore, 1904; honorary member of the Medical Society of the State of North Carolina; past president of the Person County Medical Society; physician for the Norfolk and Western Railway; served as state highway and public works physician and county physician; on the staff of the Community Hospital; died June 15, aged 71, of cerebral hemorrhage.

Frank Benson Lucas, Yreka, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; at one time on the staffs of the Los Angeles County Hospital and the Hitts Hospital, Hitts; served with the Civilian Conservation Corps and the Indian Service; died at his country home in Hornbrook June 26, aged 76, of heart disease.

George W. MacMillan, Lakewood, N. J.; College of Physicians and Surgeons, Baltimore, 1890; died June 1, aged 81, of acute myocarditis and carcinoma of the lower lip.

James Patrick Wagner, Bayonne, N. J.; Fordham University School of Medicine, New York, 1912; for many years police surgeon; president of the medical staff of St. Francis Hospital, where he had been a member of the staff for thirty years; died June 27, aged 54, of coronary occlusion.

Lucy Agnes Marraffino @ New York; Columbia University College of Physicians and Surgeons, New York, 1931; diplomate of the National Board of Medical Examiners; associate visiting physician, Misericordia Hospital; assistant visiting physician at the Gouverneur Hospital, where she was examining physician for the draft board; died in the New York Post-Graduate Medical School and Hospital June 6, aged 37, of postoperative embolus following cholecystectomy for cholelithiasis.

Irvin Hollis McDaniel, Alto, Texas; Chattanooga (Tenn.) Medical College, 1897; died May 15, aged 75, of Hodgkin's disease.

Onis Oliver Melton, Lowell, Ind.; University of Louisville (Ky.) Medical Department, 1910; served during World

War I; on the staff of St. Margaret Hospital, Hammond; died June 4, aged 59, of coronary thrombosis.

James Monroe Middleton, Many, La.; Vanderbilt University School of Medicine, Nashville, Tenn., 1890; served as a member of the first town council; one of the organizers of the first local bank, acting as vice president; chairman of the local school board for many years; president of the Sabine Parish Board of Health; died June 5, aged 77.

Elliott D. Moore, New Philadelphia, Ohio; Western Reserve University Medical Department, Cleveland, 1888; charter member of the New Philadelphia Rotary Club; formerly director of the Tuscarawas Savings and Loan Company; once president of the board of education; died June 15, aged 80.

John Marshall Mozley, Johnston City, Ill.; St. Louis College of Physicians and Surgeons, 1891; for many years city health officer; died June 26, aged 81, of carcinoma of the lungs.

Paul Nichols, New York; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1929; member of the Medical Society of the State of New York; died in the Mount Sinai Hospital June 29, aged 44, of acute leukemia.

Clarence Edgerton Owens, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1910; member of the South Carolina Medical Association; died in the South Carolina Baptist Hospital May 27, aged 57.

Joseph N. Palt, Kenosha, Wis.; Illinois Medical College, Chicago, 1905; died in St. Catherine's Hospital May 31, aged 63, of cerebral hemorrhage.

Henry May Pond, Alameda, Calif.; University of California Medical Department, San Francisco, 1880; died in the Alameda Hospital June 6, aged 88, of arteriosclerotic heart disease.

Joseph Aloysius Richardson, Washington, D. C.; Medical College of the State of South Carolina, Charleston, 1917; died June 15, aged 55.

George J. Sabatier @ New Iberia, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1889; served on the staff of the Dauterive Hospital; a director of the New Iberia State National Bank; died June 17, aged 81, of coronary thrombosis.

Norman A. Saylor, Philadelphia; Hahnemann Medical College of Philadelphia, 1880; died in the Philadelphia State Hospital, June 6, aged 86, of cardiac decompensation and chronic myocarditis.

James W. Scott, Detroit; Michigan College of Medicine and Surgery, Detroit, 1896; member of the Michigan State Medical Society; formerly on the staff of Michigan Home and Training School, Lapeer, Mich.; died in the Mount Carmel Mercy Hospital June 25, aged 75, of myocarditis.

Frank Winfred Shelton @ Independence, Kan.; Kansas City (Mo.) Medical College, 1904; served during World War I; colonel, medical reserve corps, U. S. Army, not on active duty; died May 15, aged 68, of coronary occlusion.

John H. Shelton, Mayfield, Ky.; University of Louisville Medical Department, 1892; member of the Kentucky State Medical Association; president of the Graves County Medical Society; on the staff of the Mayfield Hospital; died June 2 while on a fishing trip, aged 79, of coronary occlusion.

Horace Watson Sherwood, Doland, S. D.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896; member of the South Dakota State Medical Association and for many years councilor of the Second District;

past president of the Watertown District Medical Society; died in Madison August 5, aged 78, of cerebral hemorrhage.

Hugh P. Skiles, Chicago; the Hahnemann Medical College and Hospital, Chicago, 1880; died June 2, aged 92, of cerebral and cardiac arteriosclerosis, uremia and hypostatic pneumonia.

Clarence Luverne Smith @ Seattle; State University of Iowa College of Medicine, Iowa City, 1923; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; served during World War I; chief of pediatric service, Children's Orthopedic Hospital; on the staffs of the Maynard and Seattle General hospitals; died April 23, aged 46.

Edward Elmer Smith, Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1910; member of the Ohio State Medical Association; coroner of Franklin County since 1930; during World War I served in France with the 146th Ambulance Company, 112th Sanitary Train, 37th Division; active in the Ohio National Guard and had been commissioned a lieutenant colonel in the Ohio State Guard; member of the city board of health from 1925 to 1937, serving as president in 1932; died in the Grant Hospital June 18, aged 58.

William Henry Steers @ Brooklyn; Bellevue Hospital Medical College, New York, 1890; during World War I a

lieutenant colonel in the medical corps, with the twenty-seventh division in France, and later with the Army of Occupation on the Rhine; served on the staffs of the Gouverneur Hospital, New York, and Brooklyn Eye and Ear Hospital; died May 31, aged 74.

Harry Bennett Weinburgh @ Lansing, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; served during World War I; past National Commander of the Military Order of the Purple Heart; on the staffs of Edward W. Sparrow Hospital and St. Lawrence Hospital, where he died June 29, aged 62, of cerebral hemorrhage.

Fred C. Wood, Madison, Wis.; College of Physicians and Surgeons, Chicago, 1892; assistant physician, student health, University of Wisconsin; died June 4, aged 75, of coronary arterial disease.

LT. COL. BERNARD E. BULLOCK
M. R. C., U. S. A., 1912-1944

LT. (JG) CHARLES H. HENDERSON JR.
(MC) U. S. N. R., 1918-1944

KILLED IN ACTION

Bernard Eugene Bullock, Clinton, Okla.; Baylor University College of Medicine, Dallas, Texas, 1938; member of the Oklahoma State Medical Association; served an internship at the Kansas City General Hospital, Kansas City, Mo.; for two years city health officer; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 6, 1938; later promoted to major and lieutenant colonel; died in the European theater of operations June 10, aged 32, of wounds received in action.

Charles Herbert Henderson Jr., Bonny Blue, Va.; University of Virginia Department of Medicine, Charlottesville, 1943; intern at the Emory University Hospital, Emory University, Ga.; commissioned a lieutenant (jg) medical corps, U. S. Naval Reserve on Nov. 8, 1943; awarded Purple Heart posthumously; killed in action off the coast of France June 12, aged 25.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

Ache-Knock Tablets.—In a stipulation entered into with the Federal Trade Commission in October 1943, Robert A. Stewart and Marie Phillips Stewart, trading as the Ache-Knock Company, Honolulu, T. H., agreed to discontinue the following advertising misrepresentations: That these tablets will relieve or cure rheumatism, sciatica, lumbago or neuritis, cure or prevent the recurrence of headache or toothache, relieve all pain or excessive acidity, and produce no ill effects. The respondents further stipulated that they would discontinue any claim to the effect that the product is superior to aspirin unless in immediate conjunction therewith they would make appropriate comparison of the relative liability to adverse effects following the use of Ache-Knock Tablets.

Alfamint, Minrich and Pretorius Liquifier.—In October 1943 Martin W. and Marie Pretorius, trading as Pretorius Approved Products, Glendale, Calif., stipulated with the Federal Trade Commission to discontinue the following misrepresentations in the sale of these products: That either Alfamint or Minrich can be depended on to give the user renewed vitality or purge the tissues of accumulated waste; that Alfamint, in either tea or tablet form, has any diuretic action which causes it to benefit the kidneys, or that it will increase the alkalinity of the blood, in neutralizing body acids or in adding needed minerals to the body; that Minrich improves digestion, supplies all the minerals lacking in the diet, or in any way helps to prevent or lessen the tendency of such conditions as loss of teeth, irregular heart action, rickets, nervousness, indigestion, anemia, infections, thyroid disturbances, low vitality or minor skin diseases; or that the use of liquid foods prepared by means of the Pretorius Liquifier, an electric mixing device, enables one suffering from nutritional deficiencies caused by an impaired digestive system to obtain necessary vitamins and minerals from raw vegetables, fruit and other food, with resultant regeneration of sick parts of the body.

Farrand Formulas.—These were sold by N. W. Farrand, trading as the Farrand Chemical Company, Tyrone, Pa., who, in October 1943, stipulated with the Federal Trade Commission that he would discontinue the following misrepresentations about the products made from his formulas: That "Cornox" would eliminate the pain of a corn as soon as applied; that "Machineless-Heatless Permanent Wave Fluid" would be harmless to the hair; that "Waterless Shave Cream" was capable of healing facial cuts and could not be purchased elsewhere for less than \$5; that his "Inhalants" would relieve or check colds and give instant aid in nasal congestion and infections; or that his "Asthma Remedies" and "Hay-Fever Remedies" would cure or permanently correct the ailments for which they were recommended. Farrand further agreed to discontinue any advertisements for, or instructions pertaining to, his formulas for the foregoing products which failed to reveal that the preparations compounded from them might be dangerous to health.

Pow-O-Lin.—This has been advertised as a treatment for indigestion, gas pains, headaches, nervousness, dizzy spells and other ailments by the Herb Juice-Penol Company, Inc., Danville, Va. In October 1943 that concern stipulated with the Federal Trade Commission that in future advertising it would reveal that Pow-O-Lin should not be used in cases of abdominal pain or other symptoms of appendicitis. It was provided, however, that the advertisements need contain only the statement, "Caution: Use only as directed" if the directions on the labeling include a warning to the same effect. It is worth noting that in December 1937 the Pow-O-Lin concern had entered into a stipulation with the Commission to cease advertising the product as being "Capable of relieving biliousness, nervousness, indigestion and countless ills due to constipation," unless these assertions are limited to temporary relief from constipation, and that in June 1940 the Commission definitely ordered the Pow-O-Lin concern to desist from making certain unwarranted implications in its advertising, such as that Pow-O-Lin is a cure or remedy for constipation and "faulty elimination" characterized by and associated with symptoms such as biliousness, indigestion, gas pains, headaches, dizziness, pains in the back or chest, stiffness of the joints, swollen feet or ankles, nervousness, insomnia, loss of appetite or lack of energy. These two earlier actions of the Commission were dealt with in The Journal for June 21, 1941, page 2811.

Seborol Scalp Lotion and Seborol Scalp Ointment.—These are put out by the Dermatological Products Corporation, Hoboken, N. J., which stipulated with the Federal Trade Commission in October 1943 that it would cease representing that the name "Seborol" is a registered trade mark in the United States Patent Office unless it is so registered.

Vanco Ointment.—This was represented by N. Edwards and Bertha Edwards, trading as Vanco Company, Brady, Neb., as a product that would prevent, cure or penetrate to the source of a cold, draw out congestion or pain or correct a sinus condition aggravated by a cold or be beneficial in pneumonia or influenza. In September 1943 the promoters entered into a stipulation with the Federal Trade Commission, agreeing to discontinue the foregoing misrepresentations.

Vita-Rex Capsules.—These are put out by one Joseph Giannatelli, trading as Alba Bio-Products Company, Chicago, who entered into a stipulation with the Federal Trade Commission in October 1943 in which he agreed to discontinue the following misrepresentations: That this product has any value in the treatment of poor assimilation, constipation, indigestion, gaseous conditions of the stomach or intestines, functional weakness or nerve disorders; that it will enrich the blood, improve the appetite, correct gastrointestinal disorders, increase systemic resistance or produce better health; that it will protect individuals against colds, aches or a tired-out feeling, supply the body with ample nutritional substances, and possesses value as an iron preparation.

Yog-A-Lax.—That this laxative is a stomach or bowel corrective and is not habit forming were misrepresentations which the Yoghurt Products, Inc., of Seattle agreed to eliminate from their advertising in a stipulation that they entered into with the Federal Trade Commission in October 1943. They further agreed to discontinue any advertisement which failed to reveal that the product should not be used when abdominal pains or other symptoms of appendicitis are present, provided, however, that such advertisements need contain only the statement, "Caution: Use only as directed" if the directions for use on the label contain a warning to the same effect.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Arnold Garlic Tablets.—Melrose Drug Company, Cleveland. Shipped Jan. 21, 1942. Composition: essentially starch and garlic. Misbranded because statement on carton, "May be of Value in Reduction of Hypertension" was false and misleading, since product contained no ingredients to justify the statement.—[D.D.N.J., F.D.C. 779; September 1943.]

Davis Formula No. 7895.—E. R. Davis Prescription Company, Bellingham, Wash. Shipped Dec. 17, 1941, and June 23, 1942. Composition: essentially water, alcohol, potassium iodide, chloroform, sugar, and an extract of a plant drug, such as lobelia; supplementary bottle contained a solution of vitamin A. Misbranded because labeling falsely represented that this combination was an adequate treatment for asthma, hay fever, eczema or rheumatic, neuritic or arthritic pains.—[D.D.N.J., F.D.C. 780; September 1943.]

Fermilax.—Moon-Winn Drug Company, Inc., Athens, Ga. Shipped March 11, 1942. Composition: essentially sodium bicarbonate, magnesium and calcium carbonates, bismuth subnitrate and rhubarb. Misbranded because label directions provided for continuous administration, whereas product was a laxative and should not be used continuously, and because directions failed to give the dosage for children of different ages. Further misbranded because labeling failed to warn that a laxative should not be taken in case of nausea, vomiting, abdominal pain or other symptoms of appendicitis, and that frequent or continued use of a laxative might result in dependence on it to move the bowels. Also misbranded because label failed to declare an accurate statement of quantity of contents.—[D.D.N.J., F.D.C. 760; September 1943.]

Ramsdell's Sulphur Cream.—E. Fongera & Company, Inc., New York. Shipped April 22, 1942. Composition not reported. Adulterated because strength differed from that which it was represented to possess, namely, "Contains 10% Precipitated Sulphur." Misbranded because of false label representations that it would be efficacious in treating scabies, eczema, ringworm, itching, simple acne, acne rosacea, burning and soreness in eczema and water rash, as well as bald spots and falling hair.—[D.D.N.J., F.D.C. 772; September 1943.]

Vita Might Capsules.—Vital Foods Corporation, Chicago. Shipped Feb. 28, 1942. Composition (black capsules): dicalcium phosphate, pentonized iron, magnesium sulfate, manganese hypophosphite, copper pentonate, zinc sulfate and potassium iodide; (red capsules) shown by vitamin assays to contain, per capsule, 10,000 U. S. P. units of vitamin A and 1,000 U. S. P. units each of vitamins B₁ and D. Misbranded because black capsules contained smaller amounts of minerals than those declared, and labeling of both kinds bore false and misleading claims as to their supposed benefits in many disorders, such as lessened strength, poor sleep, aches, pains, nervous strain and some other things.—[D.D.N.J., F.D.C. 786; September 1943.]

FACTS ABOUT CHILDREN'S BUREAU CONFERENCE ON CHILD CARE

To the Editor:—My attention has been called to the Washington letter in *THE JOURNAL*, August 12, headed "American Academy of Pediatrics Withdraws Support from Children's Bureau." In this letter the following statement is made:

Last month a conference of child specialists and social workers here took a stand against the bureau's group care of children, asserting that group care was damaging to child welfare and actually more expensive than a foster family system of care which the conferees advocated.

This statement is false. The Children's Bureau does not conduct group care of children. We have consistently taken a position against group care of children under the age of 2 years.

On July 30 and Aug. 1, 1941 the Children's Bureau held a conference on day care of children of working mothers which adopted certain recommendations including the following: "Infants should be given individual care, preferably in their own homes and by their own mothers." The Standards for Day Care of Children of Working Mothers, published in February 1942, contains the following statement:

If it is necessary to provide for children under 2 years of age provision should be made for care in the children's own homes through supervised homemaker service or in carefully selected and supervised foster homes. Infants should not be cared for in groups.

This has been the policy of the Children's Bureau throughout the war period.

The only federal funds now available for day care services are Lanham Act funds administered by the Federal Works Agency. This summer, for the first time, applications for funds to conduct group care services for children under 2 years of age came to the Federal Works Agency and, in accordance with agreed policies, were referred to the Children's Bureau for its review. I took the position that we could not pass upon these policies for group care of infants under 2 without having the advice of the most competent experts from the fields of health, child development and social service. Accordingly I called a conference, which met on July 10, 1944. Among others attending the conference were Dr. Marian C. Putnam, director, Children's Center, Roxbury, Mass.; Dr. Milton Scnn, assistant professor of pediatrics and psychiatry, Cornell University Medical College; Dr. Benjamin Spoek, assistant attending pediatrician, New York Hospital (now Lieutenant Commander in the Navy), and Dr. Arnold Gesell, director of the Clinic of Child Development and Attending Pediatrician, New Haven Hospital.

The conference upheld the policy of the Children's Bureau with reference to infants and recommended against group care of infants under the age of 2 years. This recommendation was transmitted by the Children's Bureau to the Federal Works Agency, and the Children's Bureau is now cooperating with the Federal Works Agency in the review of an application for funds for group care of infants in San Diego, Calif., with a view to determining whether it would not be possible to provide for infants in foster families.

KATHARINE F. LENROOT, Washington, D. C.
Chief of the Children's Bureau.

TREATMENT OF POLIOMYELITIS

To the Editor:—I feel that physicians should be warned against the use of sulfonamide drugs in the treatment of poliomyelitis.

It has been noticed clinically that when paralyzes of the intestine and urinary bladder persist there are apt to be extensions of the somatic paralyzes. When urinary retention was produced in animals (monkeys) by the use of sulfonamide compounds, drugs which produced urethritis and blockage of the ureters, a more massive disease was produced two or three days sooner than that which appeared in controls simultaneously injected with poliomyelitis virus.

Roscnow had the same experience with sulfapyridine at the Mayo Clinic and reported that this drug produced an additive neurotoxic effect.

Recently an explosive epidemic of poliomyelitis occurred in a small town of northern Ohio. The number of patients that developed severe paralysis seemed out of proportion to the normal expectancy. Most of these patients had received sulfonamide drugs (information received from Mrs. Louise Bowcers, health officer, Perrysburg, Ohio).

Recently a 12 year old girl had signs of meningeal irritation, but no sign of any muscle involvement save in one leaf of the soft palate. The reflexes were hyperactive; the child was not acutely ill. The spinal fluid, checked twice, contained 220 cells, all of which were polymorphonuclears. Gram negative organisms had been reported. The prognosis seemed good whether the condition was poliomyelitis or meningitis. Sulfadiazine was started. Twelve hours later and after 12 Gm. of sulfadiazine had been given, a massive extension of paralysis suddenly developed, the throat muscles and intercostals all becoming affected within an hour. This sudden explosive extension in an otherwise nearly normal patient had not been our previous experience in this type of case.

The sulfonamide drugs are of no value in poliomyelitis. Nor does penicillin help much in our experience, although we have not noticed that it does harm.

JOHN A. TOOMEY, M.D.,
Department of Contagious Diseases,
City Hospital, Cleveland.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Right of Court Reviewing Revocation of License to Receive Evidence in Addition to Evidence Heard by Board: Disturbance of Peace as Unprofessional Conduct.—Wyatt, who was licensed to practice medicine in California, was placed on probation in 1940 for five years by the Board of Medical Examiners of California on charges of the nature of which the reported decision makes no mention. In 1942 proceedings were instituted to revoke his license for violating probation on a charge that (1) he had attempted to procure on two named women miscarriages that were not necessary to save their lives and (2) that he had been guilty of an offense involving moral turpitude, a cause of revocation, because he had been convicted of disturbing the public peace and quiet by the use of profane and indecent language. At the hearing before the board the physician and the named women denied that the women had been pregnant and that miscarriages had been procured with respect to them. A nurse, however, employed by the physician testified that she assisted the physician in performing the operations in question and that the physician curetted the wombs of both women and removed a fetus from one of them which, she testified, was about a month old. The board found the charges sustained and revoked the physician's license to practice. The physician then instituted mandamus proceedings against the individual members of the board to compel them to cancel the order revoking his license. The trial court heard all the evidence that was adduced before the board and in addition heard the testimony of another physician, who stated that a fetus of an age of 4 weeks, the age of the one the nurse testified she had seen removed, would be the size of a buckshot and the nature of such a substance could be ascertained only by the use of a microscope. The trial court found the evidence insufficient to sustain the charges preferred with the board and ruled in favor of the physician, and the board appealed to the district court of appeal, first district, division 2, California.

The board contended first that it was error in a hearing on a petition for writ of mandate for the trial court to hear evidence in addition to that heard by the board. The board argued that evidence additional to that received at its hearing could be considered by a reviewing court only (1) where evidence has been offered and improperly rejected by the administrative agency whose acts are under review, (2) where pertinent evidence was in existence at the time of the hearing before the administrative agency but could not have been at the time produced by the exercise of due diligence and (3) evidence discovered subsequent to the hearing before the administrative agency. The court, however, could not agree with this contention, relying on *Laisne v. California State Board of Optometry*, 19 Cal. 2d 831, 123 P. 2d 457. In that case the court said:

If, in the instant case, the superior court in the mandate proceeding were limited to the evidence presented before the board, or if the findings of fact by the board were conclusive on the court, then the board would be exercising the complete judicial power reserved to the enumerated courts . . . and appellant would be deprived of his constitutional right unless he had a right to go into a court of law and question the validity of that order by the introduction of any material evidence to prove that he did not commit the acts alleged.

The board next argued that its action in revoking the physician's license was justified from the evidence before it that the physician had been convicted of disturbing the peace, which is an act of moral turpitude. The vice in this contention, answered the court, is that it assumes that the offense of disturbing the peace is an act of moral turpitude. That it is an act of moral turpitude may be conceded. However, it is equally clear that

it is not ipso facto an immoral act. If and when it is claimed that such an act is one of moral turpitude the trial court may inquire into such facts as show or tend to show that the offense complained of was or was not an act of moral turpitude. In the case before us such evidence was produced by the physician. Thereafter the trial court made findings that the offense alleged to have been committed by the physician in disturbing the peace was not one of moral turpitude. That finding is conclusive on an appellate court.

For the reasons stated, the appellate court affirmed the order of the trial court directing, in effect, that the physician's license to practice be restored to him—*Wyatt v. Cerf*, 149 P. 2d 309 (Calif., 1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alcohol Lumbar Paravertebral Block in Peripheral

Vascular Disease.—Saland and Klein tried to determine objectively

(1) exactly how long one may expect vasodilatation effects to last after alcohol paravertebral block in the lumbar region, (2) whether neuritis is produced by such a procedure and, if so, how often, how severe and how long such neuritis might last, (3) whether the amount of alcohol used was a factor in producing vasodilatation or neuritis, (4) whether the use of procaine hydrochloride in sweet almond oil would reduce the incidence of neuritis and (5) whether claudication time would be altered by such therapy. The patients studied were those who applied to the vascular clinic for relief of symptoms and comprised a total of 16. The types of cases were 1 phlebitis, 1 scleroderma, 1 thromboangiitis obliterans and 13 arteriosclerosis obliterans. These cases were chosen because it was determined previously by peripheral nerve block with procaine hydrochloride that the extremity to be treated could vasodilate up completely. In 6 cases the authors used 2 per cent procaine hydrochloride followed by 5 per cent procaine hydrochloride in sweet almond oil, and this in turn by 1 cc. of 100 per cent alcohol; in 4 cases 2 per cent procaine hydrochloride followed by 1 cc. of 100 per cent alcohol; in 6 cases 2 per cent procaine hydrochloride followed by 3 cc. of 100 per cent alcohol. The authors arrive at the following conclusions: 1. The use of 100 per cent alcohol in lumbar paravertebral block is of definite value in producing peripheral vasodilatation. This vasodilata-

tion may be complete and may last for varying periods of time, even up to two years and perhaps longer. 2. The neuritis occurs more often when larger amounts of alcohol are injected; it is not too severe and in no instance has lasted more than forty-five days. 3. The use of procaine hydrochloride in sweet almond oil did not reduce the incidence of neuritis. 4. Vasodilatation occurred more often when larger amounts of alcohol were used, but the amount of alcohol was not the factor that determined how long this vasodilatation lasted. 5. There was no correlation between claudication time and the degree or duration of vasodilatation.

Trichinella Skin Tests.—Horne and Harrell used a 1:10,000 trichinella extract to perform skin tests on 700 patients, namely on 278 consecutive admissions to the North Carolina Baptist Hospital, 144 patients at the Forsyth County Hospital, 120 patients at the Guilford County Tuberculosis Sanatorium and 158 patients at the Western North Carolina Tuberculosis Sanatorium. Seventy, or 10 per cent, of the 700 patients gave positive skin reactions. This is lower than similar studies have shown in some other areas of the United States. The incidence found by skin tests was greater than that found in routine necropsies in the same geographic area. The incidence was greater among Negroes and in males but was not statistically significant in either. The incidence of positive tests was essentially the same in urban and rural groups. Patients with active tuberculosis in two sanatoriums gave a higher proportion of positive reactions (14.3 per cent) than did those without tuberculosis (7.1 per cent) in two general hospitals. Almost all of the patients with tuberculosis were in two sanatoriums; it is possible that these findings represent the result of two local, unrecognized or subclinical epidemics. Other possible explanations are that patients with tuberculosis develop skin sensitivity with much lighter infestations or retain sensitivity longer than do nontuberculous patients or that their skin is more reactive to intradermal tests in general. However, personal communications from men with experience in treating tuberculosis indicate that, in general, they have not found their patients more reactive to intradermal tests than nontuberculous persons.

Correction of External Rectus Scapularis with Contracture of Opposing Internus. P. H. Reinhardt.—p. 636.

Actinic Keratoconjunctivitis.—Scobee and Griffey found the following treatment highly satisfactory for keratoconjunctivitis or flash burn: Once the diagnosis is made, the patient is rendered comfortable by the instillation of a corneal anesthetic; 0.5 per cent pontocaine is a good, quick acting one. Following anesthesia, three instillations of 1:1,000 epinephrine at five minute intervals are made; if the patient is seen soon after the onset of ocular pain and before vascular congestion has reached a maximum, this is all that is necessary. Usually such patients gain immediate and frequently permanent relief, enabling them to return to work at once. If vasodilatation is severe the aforementioned routine is followed, and in addition the patient is given holocaine and epinephrine ophthalmic ointment to be used in the eye every three hours. One early sign of a severe burn is a miotic pupil. One per cent atropine ophthalmic ointment is instilled, but several repetitions may be necessary before mydriasis is secured. In the more severe burns, or in those which are not seen until forty-eight to ninety-six hours after the burn has occurred, more drastic therapy may be indicated. Chemosis and a mucopurulent secretion in addition to palpebral edema are all a part of the entity of flash burn and are not on an infective basis. Cold packs and holocaine and epinephrine ointment are usually sufficient. Occasionally a seda-

tive is necessary. Either corneal or conjunctival ulceration or both must be dealt with apart from flash burn. Corneal ulcers thus formed are indolent. Chemical cauterization, intravenous typhoid, vitamin therapy (riboflavin and ascorbic acid), ethylmorphine hydrochloride and methylene blue powder may be tried. As long as corneal staining persists, the eye should be kept closed with an eye pad.

Amphetamine Sulfate in Aborting Acute Alcoholic Cycle.—To test the effects of amphetamine sulfate, Miller made studies on 30 persons with suspended sentences, referred from the Cleveland Municipal Court, and 26 private patients. All were nonpsychotic, chronic alcoholic addicts treated during the acute postintoxication period. The average duration of alcoholism was sixteen years. The procedure consisted of amphetamine sulfate 10 mg. administered orally twice daily after breakfast

and after lunch, phenobarbital 1½ grains (0.1 Gm.) at bedtime and thiamine hydrochloride 30-40 mg. daily. The patients were told to include large amounts of sugar in their diet. Tepid reclining baths were ordered mornings and evenings and bed rest was recommended when indicated. In 8 control patients placebos were substituted for amphetamine sulfate; otherwise the treatment was identical. The acute drinking cycle was interrupted in 49 of the 56 patients, with subsequent periods of abstinence ranging from one to eighteen months or longer. Seven patients failed to respond satisfactorily. The cycle was not interrupted in the control group treated with placebos. It was found that physical and mental "hangover effects" were much reduced by amphetamine sulfate. Improvement in awareness, sensory perception and activity drive was observed soon after treatment. Mood and rapport were improved, patients demonstrating greater cooperation, increased accessibility and decreased negativism, thus facilitating the initiation of a rehabilitative program.

Coagulum Contact Method of Skin Grafting.—Sano had suggested the use of heparinized autogenous plasma and cell extract from the buffy coat alone or from the buffy coat admixed with erythrocytes as a means of promoting the immediate fixation of the graft and subsequent union by stimulation of cellular growth. When grafts are applied after heparinized autogenous plasma has been painted on the recipient area and cellular extract on the undersurface of the graft, a coagulum forms within a few minutes which fastens the graft in place, rendering unnecessary either sutures or special retention dressings. As a rule, vascularization of the graft follows within forty-eight hours. Thin, medium and thick split grafts as well

as full thickness grafts may all be used successfully with the method. Originally the author prepared the plasma and cell extract immediately before grafting. A modification of the original method consists in using pooled, heparinized dried plasma and dried cell extract instead of fresh autogenous plasma and cell extract in experimental skin grafting in guinea pigs. This method has all the advantages of the previously described method plus the convenience of having the plasma and cell extract immediately available for use anywhere at any time.

Surgical Treatment of Essential Hypertension.—In the past three years Berwald and Devine have employed extensive sympathectomy in the treatment of 29 patients with essential hypertension. In 24 of these Adson's subdiaphragmatic approach was used, 4 were operated on using Smithwick's dorsolumbar approach, and the remaining patient had the Smithwick operation on the right side and the Adson operation on the left side. Kidney biopsies were taken from 14 patients. All but 2 patients are alive. A careful follow-up was made on the surviving patients. The surgeon realizes that except in the most ideal cases he cannot cure hypertension, but he can effect partial cure, temporary alleviation and great subjective improvement in a large percentage of properly selected cases. The authors are enthusiastic about their results. Most of the patients were referred by clinicians who had exhausted the medical armamentarium in attempting to relieve them. Objective improvement was secured by sympathectomy in 64 per cent and subjective improvement in over 92 per cent of these cases. Sympathectomy, therefore, appears to have a real value and is here to stay until a better method is discovered. The criticism that the operation is too dangerous and strenuous for the patient compared to the relief obtained is not true. Few operations are attended with as little risk and postoperative discomfort as extensive sympathectomy.

Trichomonas Infection in Men.—According to Feo, accurate statistics are not available as to the frequency of *Trichomonas vaginalis* infection in men, but it is the opinion of many that the incidence of infection is higher than the literature would lead one to believe. The opportunity to examine a large series of men who had the provisional diagnosis of urethral discharge was afforded the author while assigned to the genitourinary section of the station hospital at Fort George G. Meade, Maryland. His studies were made on inductees found to have a urethral discharge or suspected of having one. Their ages varied from 18 to 43 years, with the mean falling between 20 and 30 years. The men were examined on arising in the morning before attending the latrine. The urethra was "stripped" and the resulting discharge collected on a cotton swab previously moistened with isotonic solution of sodium chloride. This was then mixed in 2 or 3 cc. of isotonic solution of sodium chloride. The organisms were sought by the microscopic examination of the moist films. This study revealed 144 of 926 men positive for *Trichomonas vaginalis*, a percentage incidence of 15.5. Separating this group into white and Negro men, the percentage incidence was 12 and 16.5 respectively. Of the 926 men examined, 246 were classed as having nonspecific urethritis.

The percentage incidence of nonspecific urethritis cases which may be attributable to *Trichomonas vaginalis* was 36.9. The entire group of *Trichomonas vaginalis* positive men was relatively free from all symptoms. A discharge may be noted which is characteristically small in amount, thin in consistency and of a dirty white color. Microscopically this discharge showed few epithelial cells and a moderate number of pus cells and trichomonads. Some of the stained smears were similar to vaginal ones from cases of *Trichomonas vaginalis* vaginitis as to number of trichomonads and types of bacteria. The male is the important transmitter of *Trichomonas vaginalis* infection, while the female eventually becomes a reservoir of infection.

Causes of Death in Rheumatoid Arthritis.—Rosenberg and his co-workers reviewed data on cases of rheumatoid arthritis in which necropsies were done at the Mayo Clinic. Their aim was to establish the manner in which death occurred. The series comprises 30 cases. The 30 deaths in this series are listed under three headings: (1) those which seemingly resulted from the rheumatoid arthritis itself (10 cases), (2) those which were related to treatment of the arthritis (8 cases) and (3) those from causes unrelated to the arthritis or its treatment (12 cases). An unexpectedly high incidence of rheumatic heart disease was discovered. This condition was present in 16 of the 30 patients. It was often serious and was responsible for the deaths of 7 patients. In the other 9 of the 16 cases in which rheumatic heart disease was present it was not responsible for death. Pulmonary diseases were the most common causes of death in this series. These were of varying character including pneumonia, chronic suppurative, pulmonary embolism, fat embolism and massive collapse. Renal lesions were responsible for 3 deaths. Acute pyelonephritis with oliguria was present in 2 cases and fatal amyloid degeneration in 1. Prolonged diarrhea of an unknown origin was responsible for 2 of the deaths. In 5 of the 30 cases death resulted from miscellaneous causes. These included cinchophen hepatitis, carcinoma and violence. In 2 cases the exact manner of death was unknown.

Cholesterol in Coronary Arteriosclerosis.—Observations on experimental animals indicated that hypercholesteremia of nutritional origin is a factor in the development of atherosclerosis. Shaffer attempted to determine the effect of the nutritional factor in persons without manifest endocrine disturbances on the incidence of coronary arteriosclerosis as diagnosed by clinical methods. Records of over 1,000 patients with duodenal ulcer were reviewed, and 100 patients were selected for study. The 100 patients were in the age period of 45 to 65; 95 of these were men. All of them had been under treatment for an ulcer for not less than five years. The majority had been treated intermittently and periodically for ten to fifteen years. Treatment consisted of the use of milk and cream and antacids, no patient being selected for study who had not relied on the use of milk and cream for the relief of discomfort. It was considered that prolonged intermittent use of milk implied an abnormal increase in cholesterol in the diet and met the requirement of a nutritional factor. Five hundred patients were used as a control. These were also consecutively selected from hospital admissions and were in the same age period, 45 to 65, with the same sex ratio, 475 males and 25 females. None had received peptic ulcer treatment or had any manifest endocrine

disturbance. The incidence of coronary arteriosclerosis was identical in the two groups. The author concludes that the nutritional role of cholesterol in the genesis of human atherosclerosis is of doubtful significance unless there is an associated endocrinopathy.

Changes in Fundus of Eye in Arterial Hypertension.—

Elwyn lists the changes in the fundus of the eye that may be observed during hypertension and says that the pathologic basis of these changes may be described as follows: (1) for the edema, transudation of fluid from the capillaries into the substance of the retina; (2) for the cotton wool patches, accumulations of precipitated fibrin and serum; (3) for the hemorrhages, the presence of blood in the various layers of the retina, especially in the inner layers; (4) for the sharply defined white spots, deposits of hyalin, mixed with lipids and with lipid-containing fat granule cells in the deeper layers of the retina, and for some of the more superficial white spots, a gangliform swelling of segments of nerve fibers in the nerve fiber layer; (5) for the glistening white spots, deposits of lipid and lipid-containing fat granule cells, and for the star shaped figure in the macular area deposits of hyalin and lipids along the fibers of the layer of Henle, which radiate from the macula. The changes in the retinal vessels are either functional, resulting in contraction of the arteries, or organic. The organic changes are due to either aging of the vessels or to arteriosclerosis. Only some cases of hypertension show all of the enumerated changes; in others some of them are present, and, again, in other cases perhaps none at all. In uncomplicated essential hypertension in its benign form the retinal arteries are not contracted. The changes in the fundus of the eye are only those of aging and sclerosis of the retinal vessels. In the later stages occur complications, such as a few hemorrhages, occasionally a few white spots and occlusion of branches of the central vein and artery, occasionally of the main vessels as well. A more important complication is temporary arteriospastic retinitis as part of a temporary arterial contraction in many organs. In malignant renal sclerosis or the malignant phase of hypertension all the signs of arteriospastic retinitis are apparent, that is, narrowed arteries, edema, cotton wool patches, hemorrhages, hyaline and lipid deposits and the star shaped figure in the macular area. Edema of the optic disks is also present. Because the malignant stage of essential hypertension is preceded by a long period of high blood pressure, aging and sclerosis of the retinal vessels are also seen, with angular tortuosity of the vessels, irregularity of the lumen and apparent arteriovenous compression. The sub-endothelial hyalinosis is also observed in some of the arteries of the retina and gives the vessels their white, "silver wire" appearance. In hypertension associated with eclampsia the changes in the fundus of the eye indicate the severity of the arterial contraction. As a guide to the advisability of artificial termination of the pregnancy the ocular changes are of less importance than the continuous observation of the state of the blood pressure. The arteriospastic retinitis produced in the presence of adrenal or pituitary tumors may resemble that of malignant renal sclerosis.

Fundus Oculi in Urologic Diseases with Hypertension.—Cohen presents a case of pyelonephritis in which examination of the fundus resulted in the diagnosis of neuroretinopathy. Nephrectomy and absolute rest of seven months had no beneficial effect on the secondary hypertension. The increased lesions in the fundus and the impairment of renal function indicated progression of the underlying disease. Sympathectomy improved the renal function and reduced the hypertension as well as the edema of the disk. The author also presents a case of hydronephrosis and a case of polycystic kidney. In both cases he describes and illustrates the fundus changes. The patient with hydronephrosis like the one with pyelonephritis had a neuroretinopathy of inflammatory origin, while in the case of polycystic kidney the diagnosis was bilateral chorioretinal arteriosclerosis of noninflammatory origin. The author concludes that urologic diseases, accompanied by persistent high blood pressure, usually lead to lesions of the fundus. The changes in the fundus are indicative of the severity of the underlying hypertensive vascular disease. A report on the examination of the fundus should accompany the records of cases of urologic diseases with persistent hypertension, as it is an additional aid to the diagnosis and prognosis of the disease.

Heterologous Transplantation of Human Cancers.—Greene and Lund direct attention to the capacity of some human tumors to survive and to grow in the anterior chambers of the eyes of animals. The failure of later attempts to transplant benign tumors in this manner suggested that heterotransplantability might be a characteristic property of cancer. Accordingly a series of experiments was instituted in an attempt to investigate this suggestion and, although the results to date are confirmatory, the group of benign tumors tested is not yet sufficiently inclusive to allow generalization. However, a fairly comprehensive group of cancers has been successfully transplanted. Since previous experience had shown the superiority of the guinea pig over the rabbit as a host for human tissue, this species was used exclusively in the present series of experiments. A series of 10 human cancers, including a fibrosarcoma of the chest wall, an adenocarcinoma of salivary gland tissue, a chondromyxosarcoma of the larynx, a malignant melanoma, an epidermoid carcinoma of the buccal mucosa, an adenocarcinoma of the urethra, a mammary fibrosarcoma, an undifferentiated carcinoma of the lung, an epidermoid carcinoma of the lung and a chordoma have been successfully transferred to the anterior chamber of the eyes of guinea pigs. The transplants grow progressively in the alien host and bear a close histologic resemblance to the original tumors. The authors suggest that the ability to grow cancer in lower animals affords an approach to many other problems associated with human tumors. After successful primary transplantation the cancer can be carried by serial passage to new generations of animals and subjected to a variety of investigations not permissible during residence in the human host. After preliminary growth in the anterior chamber, transfer to other body regions is readily effected.

Level of Vitamin B Complex in Diet Deficiency Level.

—Foltz and his associates present data which indicate the level of thiamine and riboflavin, especially the former, in the diet at which evidence of deficiency was detectable by a decrease in work output and the manifestation of subjective symptoms. Four subjects residing in a hospital and receiving a diet containing measured quantities of thiamine and riboflavin were trained during a period of from nine to twelve months on a bicycle ergometer, their work output during a double work period of rapidly exhausting work being recorded. During this control and training period the daily diet contained 0.43 to 0.59 mg. of thiamine per thousand calories of food, or a total daily average intake of thiamine of 1.44 mg. The urinary excretion of thiamine and riboflavin and the thiamine blood level was measured; in addition the blood pyruvic acid values were determined between seven and eight minutes after the conclusion of the last work period. The subjective complaints of the subjects were recorded as well as leg muscle tenderness and pain. A decrease in appetite occurred within three weeks in all subjects when the thiamine intake was reduced to from 0.33 to 0.38 mg. per thousand calories. A decided decrease in appetite and work output and increase in muscle tenderness and pain and desire for sleep, or fatigue, and a deterioration in mental attitude, nervous stability and alertness did not occur until four weeks after the thiamine intake had been reduced to from 0.17 to 0.21 mg. per thousand calories. The daily thiamine excretion in the urine ranged from 5 to 20 micrograms, but the riboflavin excretion except for a brief period in 1 subject did not fall below 200 micrograms. The signs and symptoms of deficiency disappeared promptly after the addition of a yeast concentrate to the diet which yielded a total daily intake of 15.5 mg. of thiamine and 6.15 mg. of riboflavin. The blood pyruvic acid values remained relatively constant and yielded no unequivocal information. In confirmation of the observations of others, the authors conclude that a daily dietary intake of approximately 0.20 mg. per thousand calories of thiamine (a total daily intake of about 0.6 mg.) results in signs and symptoms of a dietary deficiency within eight weeks. They think that the minimum daily requirement of thiamine of young men ranges from 0.33 to 0.45 mg. per thousand calories.

Effect of Sodium Alkyl Sulfate on Peptic Activity.—

Kirsner and Spitzer present additional data concerning the action in vitro of sodium alkyl sulfate on the peptic activity of human gastric juice and of a standard pepsin solution. Peptic activity and p_n were determined by methods previously indicated. The standard pepsin solution was prepared by transferring 625 mg. of granula pepsin (Pfannstiel) to a 500 cc. volumetric flask and dissolving in 1/20 molar hydrochloric acid. The solution was then diluted to volume with 1/20 molar hydrochloric acid. The results are expressed in terms of the degree of inhibition of peptic activity as compared with the control values and are recorded in tables. On the basis of their observations the authors arrive at the following conclusions: 1. Sodium alkyl sulfate greatly inhibits in vitro the peptic activity of human gastric juice and of a standard pepsin solution. 2. Optimum inhibition of the peptic activity of a standard pepsin solution at p_n 1.70 is obtained with about two and one-half minutes' incubation at a temperature of approximately 30 to 38 C. 3. The inhibition of peptic activity by sodium alkyl sulfate is apparently an irreversible effect. 4. Lactic acid in

0.2 cc. quantities exerts a slight protective action against the inhibiting effect of sodium alkyl sulfate. Similar amounts of formic, caprylic and acetic acids are ineffective in this respect. 5. Triacetin ethyl butyrate, ethyl caprylate, ethyl laurate, ethyl myristate and sodium taurocholate in 0.1 cc. quantities exert a moderate protective action against the inhibiting effect of sodium alkyl sulfate.

Cotton Hose Impregnated with Fungicide in Treatment of Ringworm.—The good results in the treatment of fungous infections of the hands and feet with copper sulfate driven into the skin by iontophoresis gave Crittenden and Joiner the idea of impregnating cotton hose with a fungicide for use in the treatment of ringworm not only because hose are in close contact with the foot during waking hours but also because treated hose bring the fungicide in contact with the shoe lining, which frequently is a source of reinfection. The experimental work was begun using solution of copper sulfate for impregnating the cotton hose. Later copper acetate was substituted for copper sulfate in cases not responding satisfactorily. Clean dry cotton socks of good grade were soaked for thirty minutes in the solution of copper salts at 40 C. After drying, the hose were ready for wear. The subjects cooperating in the study were 17 men and 1 woman, each of whom was afflicted with ringworm. They wore cotton hose impregnated with copper sulfate or acetate for periods of from one and one-half to ten months. The skin of 6 appeared normal, 11 showed improvement and 1 was worse at the end of the experiment. The acetate seemed to be more beneficial than the sulfate.

Endoscopy. E. B. Benedict.—p. 642.

Hereditary Hemorrhagic Telangiectasia.—Singer and Wolfson report a family in which typical lesions of hereditary hemorrhagic telangiectasia were present together with a positive tourniquet test. The first patient was a woman aged 80 who came under observation because of repeated spontaneous epistaxis for a period of forty years. Investigation revealed a strong hereditary tendency to telangiectasia. The woman's father had had telangiectasia and epistaxis. Reports are available on 66 members of the family, 16 of whom present telangiectasia. Telangiectasia was present in the first generation in one line but not in the second or third, and it reappeared in the fourth generation. A diagram of the family tree shows that the 2 cases described by the authors concerned nieces of the woman mentioned in the first case report. In comparing case 2 with case 1 it was noted that the tendency to bleed from the telangiectases and the tendency to easy bruising were more severe in the former. Epistaxis was more severe and the tourniquet test was more strongly positive in the latter. In case 3 the tendency to easy bruising was even more prominent and the tourniquet test was the most strongly positive of the 3 cases. A positive tourniquet test in a syndrome in which a negative tourniquet test is ordinarily considered a diagnostic criterion is noteworthy. Although only 3 members of the family could be examined, the occurrence of the unusual combination of a positive tourniquet test with telangiectasia in all of them makes it likely that both abnormal capillary manifestations were present on a hereditary basis. Whether the association of a positive tourniquet test with hereditary telangiectasia is fortuitous or is indicative of a more fundamental capillary disturbance presents a problem that necessitates analysis of the clinical pathology of capillary heredopathies. An abnormal contractility response of a capillary to injury as expressed by a prolonged bleeding time and an abnormal capillary fragility to pressure, as seen by a positive tourniquet test, represent independent variables that may be singly or simultaneously involved. Pseudohemophilia is characterized by a prolonged bleeding time but a negative tourniquet test, and hereditary purpura simplex by a normal bleeding time but a positive tourniquet test. Combinations of the two types exist. Hereditary hemorrhagic telangiectasia is a localized gross abnormality of capillaries usually not accompanied by systemic capillary dysfunction. The family reported here represents such a combination of localized gross deviation of capillary structure and increased capillary fragility. The diagnosis of hereditary capillary syndromes should depend on physiologic analysis and not on rigidly demarcated types of disorders.

*Thiouracil in Treatment of Thyrotoxicosis: Report of 72 Cases. R. H. Williams and H. M. Clute.—p. 657.

Favus in Massachusetts: Report of 2 Cases. G. E. Morris.—p. 667.

Endoscopy (concluded). E. B. Benedict.—p. 669.

Thiouracil in Treatment of Thyrotoxicosis.—Williams and Clute used thiouracil in the treatment of 72 patients with thyrotoxicosis. The 59 patients who had not had iodide therapy for one month or more were divided into three groups according to the basal metabolic rate. The decline in the basal rate was more rapid in the severe cases (basal metabolic rate +55 to 89 per cent) than in the others but required an average of five weeks to become normal, whereas in the moderately severe cases (+35 to 55 per cent) only four weeks was necessary and in the mild ones (+15 to 35 per cent) only three weeks. The lowering of the basal metabolic rate of patients who had taken iodide until the thiouracil treatment was started was slower.

All patients, however, regardless of the type of thyrotoxicity or of previous treatment, eventually attained a normal metabolic rate and a remission of the disorder. Thirty-five patients were treated with thiouracil for more than four months and 16 for more than six months. Patients maintained a normal basal metabolism, though in 4 who discontinued therapy a relapse occurred, but a remission was again obtained with thiouracil treatment. Although a transient increase in the size of the thyroid occurred in several cases, in the majority a decrease in size resulted. A few patients with malignant exophthalmos experienced an exacerbation in this process under thiouracil therapy, but with a decrease in the dosage of thiouracil and the use of desiccated thyroid an improvement resulted. One patient developed agranulocytosis; other complications consisted of a morbilliform rash, urticaria, allergic arthritis, edema of the legs, vomiting and enlargement of the submaxillary salivary glands. In the first 30 patients treated the initial daily dosage of thiouracil was usually 1 Gm., but with subsequent patients it was 0.6 Gm. daily or 0.4 Gm. In most cases, however, the dose was reduced to 0.2 Gm. daily over a period of about six weeks. Single doses usually consisted of 0.2 Gm., although they were sometimes only 0.1 Gm. When several doses were given daily they were spaced evenly. With the range of dosage employed, the drug has not been found to accumulate appreciably in the blood in spite of the presence of severe disease of the kidneys and liver. For reasons other than an unsatisfactory response in the toxic manifestations of the disease, 22 patients were subjected to thyroidectomy. The operative and postoperative course was relatively smooth, particularly in the patients treated with thiouracil for three weeks or longer preceding operation. A chemical analysis of these glands showed a great variation in the amount of drug present. There was no correlation of the therapeutic response with the level of the drug in the gland. The pathologic alterations in the thyroid gland resulting from thiouracil treatment are quite unlike the changes found after iodide therapy.

Dengue at a South Pacific Advance Base.—Stewart says that over 25 per cent of the military population of an island contracted dengue. There were no deaths, but the disease caused 80,000 sick days. Mosquitoes of the Aedes group were found in abundance on the island. Frontal headache and pain in or behind the eyes and pain low in the back are characteristic early symptoms. Chilly sensations make the sufferer use a blanket on a hot day; the chill is a true teeth-chattering chill which lasts several minutes. There may be aches and pains in or about several joints and in the muscles of the legs, arms and neck. A chain of pea size lymph nodes is felt at the base of the neck over the posterior scalenus muscles. These nodes

are not tender, vary in size and are not found in the suboccipital region as is the case in German measles. The pulse is moderately rapid during the first day, but later it becomes slow and in spite of high fever there is bradycardia. The temperature curve and the discomfort run parallel, but the pulse remains slow. During the first day or two the fever is high, but often on about the third day the temperature falls to a normal level for from several hours to two days. During this lull the patient feels better. Usually on the fourth or fifth day the fever returns. This second spike of fever is often higher than the first. Recovery is by crisis. Other types of temperature curves occur, but regardless of the type of curve the fever will not last beyond seven days and more often is over by the fifth day. This is a disease of one week's duration. The various skin manifestations are classified as rash A and rash B. Dengue must be differentiated from infectious jaundice, German measles, scarlet fever, mononucleosis, malaria, bacillary dysentery, appendicitis, mumps, meningitis, influenza, virus pneumonia and catarrhal fever. Treatment of dengue is entirely symptomatic. Reassurance, rest in bed and sedatives are important. Acetylsalicylic acid seems to control the discomfort but has the disadvantage of causing excessive sweating. Phenobarbital $1\frac{1}{2}$ grains (0.1 Gm.) at bedtime is often not sufficient. Codeine $\frac{1}{2}$ grain (32 mg.) combined with acetylsalicylic acid is required in most cases. For several days after discharge there is a feeling of fatigue and inability to carry on usual duty. This rarely lasts longer than a week. Despondency and irritability are often accompanying symptoms but almost never last longer than two weeks. The incubation period is as short as five days. No proved recurrences have been observed in a period of six months.

Intravenous Sodium Sulfathiazole.—Milles points out that conjugation of sulfathiazole to the acetylated form occurs chiefly in the liver. Taken by mouth, the drug is absorbed into the portal circulation and passes through the liver in its entirety, exposing it to acetylation before it reaches the general circulation. Administered intravenously, little of the drug reaches the liver until it has traversed the peripheral circuit, thereby exposing the tissues to the peak concentration of the drug in its original form. The author reviews observations on patients treated intravenously with sodium sulfathiazole. The drug was administered by syringe in from 5 to 20 per cent solution; the maximum dose was 3 Gm. Local tissue irritation was not noted. The daily urinary output was measured and in those who were given the drug only intravenously was examined microscopically for blood and crystals on one or more occasions. In previous observations, levels of approximately 20 mg. per hundred cubic centimeters of blood were obtained immediately after the intravenous administration of 3 Gm. of sodium sulfathiazole, falling to less than 1 mg. at the end of twenty-four hours. Observations on 46 patients who received single or multiple doses of sulfathiazole intravenously, some of whom also received sulfonamides orally, are recorded in tables. Hematuria without crystalluria occurred in 1 instance, suggesting a direct toxic effect of the drug on the kidneys. Vomiting occurred during or shortly after the administration of the drug in 3 instances. It was very likely due to the speed with which the solution was injected. Headache occurred in 1 subject who had noted the same symptom when the drug was administered orally. One patient who displayed intolerance to the drug when administered orally, as indicated by fever and vomiting, tolerated the drug intravenously without the slightest reaction. Crystalluria was not noted in any instance. There were 15 in which the drug achieved good clinical results with a total dose smaller than would be expected to be effective orally. In 9 cases the drug achieved good clinical results when administered intravenously after sulfathiazole had apparently failed when given by mouth. The drug was ineffective in 5 cases, and there were 16 cases in which the results were equivocal. The author does not deprecate the use of sulfonamides orally or locally. He urges that in those diseases and injuries in which there is a time race with infection the drug should be used intravenously initially. As in all sulfonamide therapy, regardless of the route by which the drug is administered the fluid intake must be maintained; the urinary output must be measured and recorded; the blood picture must be studied if the drug is continued for more than forty-eight hours.

Sprained Ankles.—Wright and his associates say that if an injured ankle is x-rayed and no fracture or dislocation found, a diagnosis of sprain is usually made. They show that the pathologic changes in sprained ankles are of two types: (a) complete ligamentous rupture; (b) hematoma with slight ligamentous damage. The differential diagnosis can be made only by careful physical examination or by anteroposterior x-ray inspection during manipulation under anesthesia. The best treatment for complete ligamentous rupture is the application of a walking cast for at least six weeks. Reconstructive surgery may be required in chronic cases. The essential treatment for the simple sprained ankle without serious ligamentous injury is (a) early pressure bandage, (b) limitation of the hematoma and swelling by procaine injection with massage and early use, (c) contrast baths or intermittent traction and massage for persistent swelling and stiffness.

Postvaccinal (Yellow Fever) Jaundice.—An increased incidence of jaundice was observed by deVeer and Matzner at a naval hospital in the spring of 1942. Thirty patients with jaundice were studied within a period of two months. All but 1 recovered and, with this exception, presented a clinical picture indistinguishable from the commonly termed "acute catarrhal" or "infective jaundice" of unknown etiology. The patient who died was a seaman aged 20 who was admitted to the hospital with the complaint of anorexia, vomiting, jaundice, malaise and abdominal discomfort. His past history was irrelevant. About four months prior to the onset of illness he had been immunized with yellow fever vaccine. He appeared to improve during the first few days of hospitalization under a regimen similar to that employed for other icteric patients, but then suddenly, without warning, he became very drowsy and unresponsive to questioning. The jaundice rapidly increased, the icterus index rising to 250. There was no further response to treatment, and the patient's condition became progressively more grave until he died on the eighteenth day of hospitalization (the twenty-sixth day of illness). The necropsy revealed an acute yellow atrophy of the liver in a stage at which both advanced necrosis and regeneration were present, a picture apparently identical in type with that reported in the recent outbreak of jaundice in the Army. The authors review the probable relationship of jaundice to yellow fever immunization by vaccine containing human serum. The risk of postvaccinal (yellow fever) jaundice appears to have been removed by the elimination of the human serum component formerly employed in the preparation of yellow fever vaccine. In the event of future outbreak of jaundice, it is recommended that any possible relationship to the administration of yellow fever vaccine, whole blood, plasma or related biologic products be investigated in the hope of discovering the presence of some as yet unrecognizable iatrogenic agent.

Crude Penicillium Filtrate for Local Treatment.—

Alston reports results with local use of untreated filtrate of penicillium in 24 patients. The medium in which Penicillium notatum was grown contained 3 Gm. of sodium nitrate, 0.5 Gm. of potassium chloride, 0.5 Gm. of magnesium sulfate, 0.01 Gm. of ferrous sulfate, 6.5 Gm. of potassium dihydrogen phosphate, 33.5 Gm. of disodium hydrogen phosphate, 40 Gm. of glucose and distilled water to 1,000 Gm. This is sterilized in free steam for one and one-half hours in 200 cc. amounts in 1 liter conical flasks; 5 cc. of a 10 per cent solution of sterile calcium carbonate is added to every 200 cc. of medium before inoculating. The medium should form a depth of not more than 1.5 to 2 cm. in order to expose to air a large surface relative to the volume. Incubation is at a temperature of 24 C. for eight to ten days. The mold forms a thick firm pellicle, and the culture medium below is clear. The fluid medium, after growth, is passed through a Seitz filter and is tested to make sure that the reaction is nearly neutral and that less than 0.1 per cent glucose is left. The filtrate is applied to superficial lesions by gauze soaked in it, by a cream or by portions of the recently grown mold after the fluid medium had been drained away from it. Cavities in bone which are accessible to the surface are packed lightly with gauze soaked in the filtrate and sealed. Deep sinuses in muscle and subcutaneous tissues are treated with indwelling catheters, which are carefully shortened as the sinuses heal from the bottom. Cavities and sinuses are washed out with saline solution before fresh filtrate is left in them. In 19 of the 24 patients treated the filtrate has been successful; in the other 5 success was partial, doubtful or absent. The author concludes that crude penicillium filtrate containing 4 to 10 units of penicillin per cubic centimeter may be used successfully for treating many acute and chronic inflammations by local application.

Dicoumarol in Treatment of Puerperal Thrombosis.—

Davis and Porter report results of an investigation into the possible value of the anticoagulant principle dicoumarol in obstetrics. In all, 43 cases of postpartum thrombosis were treated. They were of every degree of severity, from small saphenous lesions to bilateral femoral blockage. The cases varied so widely in severity that it was impossible to find an exact parallel series for purposes of control, but comparison with the same number of untreated cases showed a great improvement after dicoumarol. There were slight but definite amelioration of pain, a fairly rapid diminution of the edema and a shortened average stay in hospital—nineteen as against twenty-eight days. In addition the incidence of pulmonary embolism was lowered from 9 to 4 per cent, and in only 1 case was this of any degree of severity. The drug was well tolerated, and there were no untoward complications and no suggestion of spontaneous

hemorrhage. The authors conclude that dicoumarol is of value in the particular type of patient they investigated, and in these cases of established thrombosis it would appear to be fairly safe. The freedom from hemorrhagic complications may be due to the normal increase in the coagulability of the blood during the puerperium.

Nicotinic Acid in Postoperative Vomiting.—Mushin and Wood studied the effect of nicotinic acid on postoperative vomiting in two groups of patients. In one group it was given both preoperatively and postoperatively, and in the other as postoperative treatment alone. The doses were 50 mg. two-hourly. A control series was studied. In all three groups as many factors as possible were kept constant. No statistically significant effect on the incidence of postoperative vomiting was observed as a result of administering nicotinic acid.

Sulfathiazole-Proflavine Powder in Wounds.—According to McIntosh and his collaborators data from experiments, both in vitro and in vivo, indicate that the most effective antiseptic mixture now available for wound disinfection is a powder consisting of 1 part of proflavine and 99 parts of sulfathiazole. In addition to its powerful action on pyogenic cocci this mixture has a high grade of activity against Clostridium welchii, Clostridium oedematiens and Clostridium septicum, the three most frequent causal organisms of gas gangrene. The proflavine enhances the antistaphylococcus action of the sulfathiazole and at the same time affords protection against gram negative organisms. It has also the advantage of being active in serum. The value of the powder could be increased by addition of that ideal wound antiseptic penicillin. In contaminated wounds a thorough surgical toilet must be done before the powder is dusted over the surface of the wound, preferably by insufflating with a blower. The amount used should be just sufficient to give a slight coating on the surface—equivalent to 0.5 Gm. to 4 square inches. Good results have been obtained by treating on alternate days. Wounds usually become dry in four to five days, coinciding with the suppression of the infection. The part of this paper which reviews the clinical application of the sulfathiazole-proflavine powder presents comments on results obtained by Hudson and Parkes, by Patey and McMullen and by Pile. These reports demonstrate the preventive and curative action of the powder in wounds.

Sulfathiazole-Proflavine Powder in War Wounds.—

Feggetter describes the results of treating a variety of war wounds with sulfathiazole-proflavine powder. In fresh wounds thorough surgical treatment was carried out, the powder was insufflated and most wounds were sutured completely; some had a small drainage tube inserted into potential dead space for four to seven days. The sutured wounds healed by first intention. In the others a small area of granulation remained around the site of the drainage tube which healed within a week. Older wounds in patients who arrived without preliminary treatment, two to three days after wounding, were already infected and the surgical treatment here consisted of incision of skin, fascia and muscle, removal of foreign matter and insufflation of sulfathiazole-proflavine powder; the wounds were left open without sutures, and large wounds with or without fractures were encased in plaster. These wounds healed well. There were 8 patients with gas gangrene. Of 4 treated elsewhere 3 had amputation and died, and 1 recovered. The other 4 were treated by incision, excision of muscle and insufflation of sulfathiazole-proflavine powder; of these, 3 healed locally and 1 required amputation later for sepsis, the gas gangrene being controlled.

In 50 wounds treated elsewhere the indication for operation was spreading inflammation or persistent suppuration. Following enlarging of the entry wound, removal of foreign bodies and debris, and insufflation of sulfathiazole-proflavine powder, the wound was left open. In all 50 cases the spread of infection was arrested and the wounds quickly healed. In 7 amputations, in some of which the amputation site had to be approached through edematous or frankly purulent muscle, flaps were fashioned, sulfathiazole-proflavine powder was insufflated and wounds were loosely sutured with or without tube drainage; these wounds healed well. Four second degree burns of moderate extent have been treated with sulfathiazole-proflavine powder. There seemed to be much less local infection than in the cases treated with other powders and cream. Complete bacteriologic investigations could not be arranged during the treatment, but sulfathiazole-proflavine powder is certainly the best wound antiseptic that the author used. The local use of sulfathiazole-proflavine powder should enable many wounds to be sutured with safety.

Homologous Serum Jaundice.—MacCallum and Bauer describe attempts to isolate an icterogenic agent from cases of serum jaundice and from a known icterogenic serum obtained from a blood transfusion depot. Experiments were made on animals and on human volunteers. Although the number of subjects used in each group was small, the following tentative conclusions can be drawn: 1. Serum from a presumed case of homologous serum jaundice was icterogenic on the seventh day after the onset of jaundice but not fifty-nine and one hundred and thirty-four days later. 2. A batch of yellow fever vaccine containing pooled human serum obtained from a blood bank produced jaundice in from 30 to 40 per cent of those inoculated with it. Inoculation of the same serum by itself produced hepatitis and jaundice in a similar percentage of volunteers. 3. The icterogenic agent survived heating at 56 C. for one hour and was still very active after storage for fourteen months in the dried state. 4. A number of those inoculated with icterogenic serums showed evidence of liver damage of insufficient severity to produce jaundice. 5. Results obtained on 2 volunteers are not inconsistent with the view that the icterogenic agent present in the blood in homologous serum jaundice is capable of multiplying in tissue culture.

Congenital Defects in Infants Following Rubella During Pregnancy.—Maternal rubella in the early months of pregnancy may be followed by congenital defects (cataract, heart disease, deaf-mutism, microcephaly and glomerular sclerosis) in the infants born subsequently. This had been pointed out by Swan and his collaborators in the *Medical Journal of Australia*

(2:201 [Sept. 11] 1943; abstr. *THE JOURNAL*, Dec. 25, 1943, p. 1144). Since then the authors have had the opportunity of studying a further series of cases. They report 12 cases of rubella (German measles) during pregnancy. Ten of the subsequently born infants exhibited congenital defects such as cataract, deaf-mutism, heart disease, microcephaly and obliteration of the bile ducts. All of the 10 mothers with congenitally defective children had contracted rubella within the first three months of pregnancy. The mother of an infant with congenital cataract, heart disease and microcephaly was unaware of any disease during pregnancy. One woman who had mumps and rubella at a late stage of pregnancy gave birth to a normal infant. Every effort should be made to acquaint the general public with the possibility that maternal rubella early in pregnancy may be followed by congenital abnormalities in the infants born subsequently. Their reasons are as follows: 1. German measles is looked on as such a mild disease that many patients fail to see a medical attendant. 2. If they were aware of the danger, pregnant women would take every care to avoid contact with patients suffering from rubella. 3. If the disease was prevalent, such women could report to their medical attendants with a view to receiving prophylactic inoculations of serum.

Dextrose Tolerance Test After Cranial Trauma.—Roth performed sugar tolerance tests on 45 patients with cranial injuries. The usual number of tests made was three or four. All patients with commotio cerebri or with injuries associated with it showed elevated values in dextrose tolerance tests. This disturbance in the carbohydrate metabolism is manifestation of an impairment of the corresponding sympathetic centers. A normal blood sugar tolerance curve, provided the tolerance test is made not later than the third day, rules out a traumatic lesion of the brain. The degree of elevation of the blood sugar values and of the derangement of the blood sugar curve does not parallel the severity of the cerebral lesion. Repetition of tolerance tests at intervals of from four to eight days are more valuable than a single test. The blood sugar curve becomes normalized the sooner, the milder the cerebral commotion. The severity of the commotion is indicated not by the maximal height of the curve but rather by the time that elapses before normalization of the curve. The tolerance test is a more precise indicator of the disturbances caused by the commotio cerebri than are the complaints of the patient. In the majority of cases the blood sugar curve still reveals elevated sugar values when the subjective symptoms have already subsided. In only 2 cases did subjective complaints persist after the sugar curve was normal again, and 1 of the patients was a psychopath. The tolerance curve is positive even in mild cases in which subjective symptoms are absent or obscure. Thus it is of value when the history is inaccurate or unreliable, and even more important from the prognostic and therapeutic points of view. The author allows the patients to get up as soon as the tolerance test curve is normal unless other symptoms contraindicate it. It is no longer necessary to keep patients in bed for three or four weeks. Another advantage is that the test is

objective and an aid in possible medicolegal questions. It is a valuable addition to the classic symptoms but should not be overemphasized to their detriment.

*Plasmatic Activator of Prothrombin. R. Feissly.—p. 925.

Plasmatic Activator of Prothrombin.—Feissly says that if a clear plasma is prepared by centrifugation from blood that has been rendered noncoagulable and if then the fibrinogen is extracted, a plasma rest is obtained which contains a thrombin forming system. Plasma rests are capable of producing an active thrombin. The author is concerned with the question: Is the plasmatic activator of prothrombin a protease or does the plasma contain an autonomous thermolabile thrombokinase, independent of the plasmatic proteases which are also thermolabile? He presents records of the results of experiments which were carried out to solve this problem. These lead him to the conclusions that (1) an autonomous plasmatic thrombokinase exists, (2) this thrombokinase does not possess proteolytic properties and (3) the plasmatic proteases cannot be considered as activators of prothrombin. The author lists observations which demonstrate the independence of the proteases and of the plasmatic thrombokinase. The proteases are inactivated at 56 C., but a temperature of 60 C. is necessary to inactivate the plasmatic thrombokinase. An "absorbed plasma," free of proteases but with the thrombokinase function still preserved, can be obtained by submitting an oxalated plasma to the action of certain mineral absorbents. A solution containing prothrombin and the proteases of plasma can be obtained by elution of the precipitated absorbent. These and other observations recounted in this report seem to oppose the notion according to which a proteolytic enzyme must be considered as the plasmatic activator of prothrombin. On the contrary, this activator appears to be a substance devoid of proteolytic properties and probably a thermolabile phosphatidoproteic link.

- *Rheumatic Fever in Cuban Children. R. Pérez de los Reyes, H. de la Torre, J. Labourdette and J. A. Junco.—p. 3.
Typhoid Osteitis: Case. J. G. Cabrera Calderín, R. Pereiras and J. M. Labourdette Scull.—p. 40.

Rheumatic Fever in Cuban Children.—Pérez de los Reyes and his collaborators reviewed the clinical electrocardiographic and orthographic records of 100 children with rheumatic fever observed in the Department of Heart Diseases of a Municipal Hospital for Children in Havana. The incidence was 30 per cent higher in girls than in boys. It was greater for children between the ages of 5 and 11 than in either younger or older children. The disease was rare in children belonging to well-to-do families. It was more frequent in white children than in either mulattos or Negroes. The hyperacute form with death within one or two weeks was observed in 2 girls. The acute form of the disease was observed in 10 boys and 3 girls, the subacute form in 4 boys and 4 girls and the chronic form in 33 boys and 30 girls. Myocarditis occurred in 28 boys and 34 girls, pancarditis in 2 boys and 4 girls, valvulitis in 43 boys and 47 girls and pericarditis in 1 boy and 2 girls. The electrocardiogram was normal in only 8 cases (in 5 boys and 3 girls). There were the following electrocardiographic changes: sinus arrhythmia 6 per cent, complete arrhythmia 1 per cent, right deviation of the axis 20 per cent, left deviation of the axis 6 per cent, a P wave either widened or high 9 per cent, a P wave either bifid or biphasic 23 per cent, an increased PR space 20 per cent, a "notched" 2-R-5 complex 15 per cent, bundle-branch heart block 1 per cent, an unlevelled ST space 2 per cent, a low voltage T wave 18 per cent, a negative T wave in two leads 7 per cent and auriculoventricular dissociation 3 per cent. Orthodiagram examinations were carried out on 32 boys and 32 girls. The size and form of the cardiac area was normal in 3 boys. It was greatly increased in 14 boys and 5 girls, moderately increased in 13 boys and in 17 girls and

slightly increased in 2 boys and 10 girls. Half the number of patients in each group had anemia of either the first or the second degree. In none of the cases had a tonsillectomy been previously performed. Sixteen boys and 18 girls suffered with chronic tonsillitis and 3 boys and 6 girls with local infection in the mouth. Adenoids were observed in 1 boy and 2 girls. One boy had sinusitis and another boy had chronic otitis media. The basic therapy consisted of sodium salicylate, which should be administered at proper doses early in the course of the disease and for as long as it is necessary. Rest of the patients for long periods, removal of focal infection, administration of a proper diet, vitamins, and sojourn of the patients in proper climate are useful adjuvant measures.

Changing Concepts in Etiology and Treatment of Peptic Ulcer.—Best reviews the etiology of peptic ulcer and favors the vascular theory. The formerly popular antacid method of treatment is going out of favor. From observations on 37 cases a regimen is offered which consists of frequent bland meals, sufficient exercise, emotional control, adequate warmth and minimal or preferably no medication.

Scarlet Fever.—Fan and Pi say that during the past seven years two epidemics of scarlet fever occurred in Tsinan. This report deals with an analysis of 309 patients with scarlet fever observed in the Chcdoo Pediatric Division between 1928 and 1937. Scarlet fever was rare in infants of less than 1 year. Most of the patients were from 2 to 6 years of age. A single throat culture revealed *Streptococcus haemolyticus* in 80 per cent of the cases. The onset was abrupt. Fever, sore throat, vomiting and skin rash were the common early symptoms. Convulsions, abdominal pains, chills and delirium were uncommon. Complications such as tonsillitis, cervical abscesses, otitis media and nephritis were fewer in the serum treated group. There was 1 girl who had two attacks of scarlet fever within four years. Five patients with nephritis completely recovered. The mortality rate for serum treated patients was 13.9 per cent and for non-serum treated patients 24.6 per cent. Serum sickness occurred in 33¼ per cent of the 72 serum treated patients. The source of infection could be determined for 70 patients. Fifty of these contracted the disease from their family members and 20 from their school mates or neighbors. Of 95 adults exposed to scarlet fever, 28 contracted the infection and 5 died. Of 233 children exposed to scarlet fever 95 contracted the disease, and of these 32 died.

Book Notices

Medicine and the War. Edited by William H. Tallafiero. Cloth. Price, \$2. Pp. 193, with illustrations. Chicago: University of Chicago Press, 1944.

This book owes its origin to a series of lectures given by members of the Division of the Biological Sciences of the University of Chicago in the spring of 1943 under the sponsorship of the Charles R. Walgreen Foundation for the Study of American Institutions. The various subjects (historical background, food, chemotherapy, malaria, insect carriers, shock and blood substitutes, aviation medicine, cerebral injuries, psychiatry and chemical warfare) are well chosen and arranged in a logical sequence. The result is a well rounded picture of medical advances important in modern warfare and, on the other hand, of the many problems modern warfare poses to medicine. However, if the reader expects the title of the book to refer to the present conflict exclusively he will be somewhat disappointed. The desire to make the audience understand the matter under discussion (the book anticipates lay readers) often shifts the emphasis to outlines of physiologic, pharmacologic and pathologic theories. Moreover, in a good many cases such facts and documentation as are given relate to experiences of the last war and the prewar period. The connection with the present war thus tends to be loose and, as a whole, the book has a decidedly academic character. There is, on the other hand, a wise restriction to relatively few but illustrative examples. The chapter on neurologic and psychologic effects of cerebral injuries, which is mainly devoted to the consequences of lesions of the frontal lobes, may be cited as an instance of lucid presentation.

The book has an advantage over similar popular publications in avoiding exaggeration and overdramatization. The calm and dignified tone that was to be expected from the distinguished contributors does not allow the reader to forget that war is an evil, however necessary it may be and however great a stimulus to medical progress.

Mitosis: The Movements of Chromosomes in Cell Division. By Franz Schrader, Professor of Zoology, Columbia University, New York. Cloth. Price, \$2. Pp. 110, with 15 illustrations. New York: Columbia University Press, 1944.

This monograph reviews critically the work on the mechanisms of cell division. The distribution of chromosomes to new cells is a complicated but well ordered process, a thorough understanding of which is essential to advance in the study of problems of cell behavior. A number of hypotheses have been advanced to explain the movements of chromosomes, but to the author no final solution is in sight. The trouble seems to be "that nearly all the hypotheses have been built around the idea that a certain, single type of force underlies all mitotic activity." It now seems clear that "mitosis is comprised of a great complex of different mechanisms." The review ends constructively in the recommendation that at present research better be concentrated on single, limited phases of mitosis in favorable species rather than directed to the immediate complete analysis of the whole mitotic cycle.

Absence from Work: Prevention of Fatigue. Conditions for Industrial Health and Efficiency, Pamphlet No. 2. Issued by the Industrial Health Research Board of the Medical Research Council. Paper. Price, 3d. Pp. 20, with 4 illustrations. London: His Majesty's Stationery Office, 1944.

This pamphlet is the second in a series issued by the Industrial Health Research Board of the Medical Research Council intended to improve and safeguard industrial health and efficiency. It states at the outset that industrial productivity is dependent on the health, efficiency and enthusiasm of the workers. The factors leading to absence from work as they relate to conditions inside the factory, outside influences and the status of the workers' minds and bodies are all succinctly listed. In this last connection, certain measures calculated to relieve boredom and indifference are described, such as rest periods, judicious use of music, the introduction of competition and a definite knowledge of what the process means to the finished product. Individual workers, joint productive committees and

works councils all must contribute to improve attitude, work environment and interest in healthful living. The effect of fatigue on productivity expresses itself in lowered output, lowered quality of work, more accidents and behavior of workers. Causes of fatigue are the length and intensity of the work period, working conditions, lack of suitable incentive and improper rest and relaxation away from the plant. Each suggests a remedy, and the remedies are sensibly presented.

Psychiatry for Nurses. By Louis J. Karnosh, B.S., Sc.D., M.D., Associate Clinical Professor of Nervous Diseases, School of Medicine, Western Reserve University, Cleveland, and Edith B. Gage, R.N. In collaboration with Dorothy Mereness, A.B., M.N., R.N., Instructor of Psychiatric Nursing, Neuropsychiatric Division, City Hospital, Cleveland. Second edition. Cloth. Price, \$2.75. Pp. 339, with 38 illustrations. St. Louis: C. V. Mosby Company, 1944.

This is one of the most practical textbooks on psychiatry for nurses. Here is a book that is written clearly and simply. The authors fully realize that their subject must be presented concisely and with utmost simplicity because of the many other subjects the nurse must take during the course of her training. With this point of view the reviewer heartily agrees. After each of the twenty-nine chapters there is a list of questions which can be used to good advantage. There is also a bibliography. This book is highly recommended to all nurses, both undergraduate and graduate, and also to general practitioners of medicine.

A Manual of Physical Therapy. By Richard Kovács, M.D., Professor of Physical Therapy, New York Polyclinic Medical School and Hospital, New York. Third edition of "Physical Therapy for Nurses." Cloth. Price, \$3.25. Pp. 309, with 118 illustrations. Philadelphia: Lea & Febiger, 1944.

This is the third revised edition of a book formerly published under the title "Physical Therapy for Nurses." It is divided into six parts: Part I is an introduction dealing with physical forces and the history of physical therapy, part II deals with heat and light, part III with electricity, part IV with hydrotherapy, part V with massage and exercise and part VI with applied physical therapy. The sections on heat and light and on electrotherapy have been considerably revised, and new illustrations have been added in this edition. The section dealing with massage and exercise has been amplified, and a new final chapter on "Physical Therapy in War" is a timely addition. This textbook should continue to serve as a valuable manual for teaching physical therapy to nurses, and it can also be considered a useful volume for the physician who is unfamiliar with physical medicine and who desires a rapid survey of the elementary aspects of the field. The revisions which have been made are distinctly worth while. Kovács's facile pen has made another valuable contribution to the broad field of physical medicine.

The Psychology of Women: A Psychoanalytic Interpretation. By Helene Deutsch, M.D., Associate Psychiatrist, Massachusetts General Hospital, Boston. Foreword by Stanley Cobb, M.D., Bullard Professor of Neuropathology, Harvard University, Boston. Volume I. Cloth. Price, \$4.50. Pp. 399. New York: Grune & Stratton, Inc., 1944.

Those who are familiar with the writings of Helene Deutsch have come to expect from her publications sound, carefully studied and clinically illustrated scientific observations. The present volume lives up to such expectations in every particular. The author states in the preface that "the purpose of this book is to explain the normal conflicts. We know that the degree of psychic health is not determined by the absence of conflicts but by the adequacy of the methods used to solve and master them." Exhaustive case material is presented to illustrate the validity of conclusions reached from psychoanalytic investigation into problems of feminine development. In the present work, which is the first of two volumes, the author discusses the individual development and personality of women. This volume contains ten chapters, on prepuberty, early puberty, puberty and adolescence, menstruation, eroticism, the feminine woman, feminine passivity, feminine masochism, the "active" woman, the masculinity complex, homosexuality and the influence of the environment. The bibliography and the index are excellent. This book not only will interest the psychiatrist, the psychologist, the physician and the student but may be read with understanding and profit by mothers and young women who hope to be mothers.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

REFRACTORY EDEMA OF LEGS

To the Editor:—A patient complains of swelling and pain in the legs, dyspnea and thirst at night. She has had these complaints for about six months. The history is essentially normal. The patient is a woman aged 60 weighing 190 pounds (86 Kg.). The heart sounds are poor; no murmur is audible. The blood pressure is 140/78, the pulse rate 90. The lungs are clear, and the abdomen is normal. The legs show a number of large varicose veins and are edematous. There are on each leg a number of bright red areas varying in size from 0.5 cm. to 1 inch. They are tender, superficial and, on palpation, feel like thrombotic veins. These areas are found between the knees and the ankles. The blood sugar is 104 mg.; urine, blood and electrocardiogram are normal. Digitalization has not improved the legs, although it has helped the dyspnea and reduced the pulse rate to 78. Mercupurin, foreign protein therapy and aminophylline have also been tried. What additional therapeutic measures may be suggested?

M.D., Pennsylvania.

ANSWER.—The stubbornness and resistance to treatment in this case at once suggest Quincke's disease, or angioneurotic edema. This condition is characterized by such swelling as is described together with the itching. It is assumed in this diagnosis that the red areas are in the nature of urticarial wheals. If these areas come and go rapidly they are almost sure to be allergic in origin. The dyspnea and thirst may represent swelling about the throat and palate. Has such swelling been observed in this case? The treatment of this disease is quite unsatisfactory. An allergen must be sought, and the usual measures that are employed against allergic disorders are used, but much is left to be desired.

Other circulatory disturbance in the lower part of the legs must be considered. Circulatory disturbance in the lower part of the legs will not explain dyspnea, but the improvement of the dyspnea under digitalis administration suggests the presence of an associated deficiency of the coronary circulation. Dyspnea due to congestive heart failure is not likely with clear lungs. The presence of varicose veins, swelling and pain suggests acute thrombophlebitis. If the red and tender areas are really thrombosed veins, support is given to this diagnosis. At any rate, if the red and tender areas are inflammatory and not allergic they should be treated by rest and elevation of the legs. The use of a sulfonamide might hasten the control of the active infection. The addition of ammonium chloride to the therapeutic measures already used might be helpful. After the subsidence of the acute inflammatory process the circulation should be restored as far as possible.

SYPHILITIC RELAPSE OR REINFECTION

To the Editor:—A diagnosis of primary syphilis was made on a Negro soldier, aged 18, by means of a positive darkfield examination of penile ulcer. Blood serologic tests were negative at this time. Treatment was begun immediately and followed the routine mapharsen injections twice weekly for ten weeks, with bismuth weekly the first five weeks. The chancre healed rapidly and completely. Treatment was started on Jan. 12, 1944. Because the patient neglected to take his treatment promptly on every occasion, the number of mapharsen injections was increased to twenty-five and completed April 24. Three days later the first of a series of six weekly bismuth injections was begun. The next day the patient noticed a lesion on his penis in a different location from the original one. Darkfield examination revealed the lesion to be teeming with spirochetes. Would you kindly interpret this case for me and suggest a course of treatment.

Lieutenant, M. C., A. U. S.

ANSWER.—In this case the question of differential diagnosis between reinfection and monorelapse would have to be considered. Ordinarily, with a monorelapse the process returns on the site of the old primary lesion. That is not necessary, however. Nothing is said as to the condition of the draining lymph nodes and whether the same chain of nodes is involved in the second infection that was involved in the first.

As the patient in question was irregular in his treatment, the chances are that he has a relapse type of syphilis. In an early relapse like this, one would find spirochetes locally just as with a chancre.

A condition like this should be treated as acute syphilis. There should be no difficulty in getting treatment with penicillin, hospitalization and intramuscular injections in the buttocks as is recommended for this disease when penicillin is employed.

INTERMITTENT BURNING OF PALATE

To the Editor:—A woman aged 32, the mother of 2 children, for the past four years has complained of an intermittent burning in the hard palate. At times she insists that small blisters and cracks appear, but I have never been able to identify them. Diet is adequate, and careful blood study has not revealed any abnormalities; there has been no response to treatment with adequate amounts of vitamin B complex and multivitamin preparations. The burning is bilateral and involves the anterior portion of the palate. The complaint began following a cervical amputation for severe erosion and laceration. Preceding the operation the patient complained of numbness and tingling in the fingers, which cleared up following the operative procedure. The patient otherwise is neurotic and of poor emotional control, with frequent outbursts against children and husband. When situations arise which provoke emotional response on her part, the burning in the mouth becomes worse. However, she refuses to accept the idea of psychogenicity or permit psychotherapy. The burning is somewhat relieved by application of topical anesthesia. An oral surgeon has advocated alcohol injection of the palatine nerves. Although it is probable that this patient's complaint is largely hysterical in nature, in view of the relief with topical anesthesia and rejection of a more fundamental approach via psychotherapy do you think alcohol injection may prove beneficial? Are any harmful sequelae likely to ensue? Any other suggestions will be welcomed.

M.D., New York.

ANSWER.—Does the patient have any trigger zones in the tonsillar regions? Has she free acid in her stomach contents? From the description the patient is not afflicted with a neuralgia but with a neurosis. It is doubtful that an injection of alcohol into the foramen rotundum or in the gasserian ganglion would have an anesthetizing effect. Although the palatine nerves are branches of the maxillary division of the trigeminal nerves, they are supposed to be related to the 7th and 9th cranial nerves. In this case it is bilateral and both sides would have to be injected. Harmful sequelae are not likely to ensue. Sight must not be lost of the fact that if this patient is neurotic and does get a permanent anesthesia she may be quite disturbed about the numbness. The topical applications might be continued. If the burning becomes uncontrollable, one side may be injected. Before it is done, however, the patient should be fully acquainted with the fact that her palate may become numb.

PHOTOELECTRIC COLORIMETERS

To the Editor:—What is the present status of photoelectric colorimeters? Which is the best make at the present time for general laboratory use?

M.D., Ohio.

ANSWER.—The amount of a substance in solution is measured in a visual type of colorimeter by matching the brightness of two adjacent fields. The accuracy of the determination depends on the sensitivity of the eye as well as other factors, such as fatigue and after-images and individual variation. It is often difficult to check readings satisfactorily, especially with different observers. In a photoelectric colorimeter most of these sources of error are eliminated. Here the concentration of a substance in solution is measured by the amount of deflection of the pointer of a sensitive electric meter. If the instrument meets certain requirements (see Bureau of Standards Letter Circular LC-473), readings are rapid and accurate. All good photoelectric colorimeters provide also for the use of color filters. These add to the usefulness of the instrument by limiting the transmitted light to a relatively narrow spectral region in which there is the greatest change in transmission with a change in concentration of the substance to be determined. Photoelectric colorimeters are rapidly replacing the visual type in most laboratories. The main problem is expense, but accurate and well constructed instruments are now available at moderate prices. The Klett-Summerson and the Ceico instruments are both satisfactory and can be highly recommended for routine clinical laboratory use.

TRAUMATIC FRACTURE WITH INTACT PERIOSTEUM

To the Editor:—Is it possible to have a fracture due to external trauma without loss of continuity of the periosteum?

Lieutenant, M. C., A. U. S.

ANSWER.—It is possible to have a fracture due to external violence without loss of continuity of the periosteum. This membrane in youths, adolescents or young adults is highly vascularized, pliable and elastic. The bone beneath, therefore, may be fractured across or in a spiral from external twisting violence, permitting the periosteum to escape tear. This does not often happen. There may be only small tears in many cases. When the periosteum remains intact a hematoma forming between it and the underlying cortex is confined and after organization forms the basis for late developing callus formation. This mechanism is illustrated in so-called march fractures or "pied forcé," in which at first the fracture plane does not appear in the roentgenogram but comes out three to six weeks later with callus formed beneath the raised periosteum.

STATEN ISLAND, N. Y.

In a preliminary report¹ the influence of penicillin therapy on the clinical manifestations and serologic reactions of patients with early syphilis was presented. The report was based on the results of a curtailed period of observation of a group of 4 patients. It is our purpose in the present paper to record the findings of post-treatment observation of the original group for periods in excess of three hundred days. It is also desired to record certain items of information which have resulted from the treatment of an additional 100 patients.

REVIEW OF ORIGINAL GROUP

Of the group of 4 patients the records of whom formed the basis for the preliminary report,¹ all have been maintained under observation. It will be recalled that these patients displayed dark field positive lesions of early syphilis at the time of treatment. The therapy consisted of an intramuscular injection of 25,000 units of penicillin administered at four hour intervals for forty-eight injections. The total amount of the product utilized was 1,200,000 units and the total time of therapy was about eight days. No other antisyphilitic medication has been employed. The post-treatment observation has consisted of a clinical and serologic examination at weekly intervals for the first six months and monthly observations thereafter. A spinal fluid examination was carried out at the completion of six months post-treatment observation.

Three members of the original group experienced a rapid healing of penile ulcerations and attained seronegativity within the initial three months of observation. These patients have remained clinically and serologically negative up to the present. The remaining patient has displayed circumstances which warrant discussion.

In this patient the penile lesion healed promptly and the serologic tests were recorded as negative on the

71st day. This situation maintained until the 286th day of observation, at which time strongly positive reactions were recorded in all test procedures. At that time the patient was under treatment for specific urethritis in a distant clinic. After some delay the patient was again made available for study and was found to have a single ulcerative lesion, on an indurated base, located on the inner surface of the lower lip. The regional lymph glands were enlarged and firm. There was no other evidence of involvement of skin or mucous membranes or of general adenopathy. Dark field examination of secretions secured from the lesion, after all precautions had been taken to avoid the contamination of the specimen by mouth spirochetes, was considered to be positive for *Treponema pallidum*.

Although this patient is being classed as a treatment failure, the probability of reinfection is inescapable. Retreatment with penicillin has been carried out.

Table 1 shows the serologic record of the first patient treated with penicillin for early syphilis. Table 2 shows the complete serologic record of patient 4, including serologic relapse or serologic upstroke accompanying reinfection.

In continuing the general study a series of approximately 100 patients have been treated in essentially the same manner as was employed in the original group. Although the post-treatment period of observation has not been of sufficient duration in a large enough group to warrant the drawing of conclusions, some interesting observations may be presented at this time. These are presented as informative material only and with the understanding that they may or may not be substantiated by more complete data.

The principal clinical features of the study may be summarized in the following manner:

The therapy has consisted of an intramuscular injection of 20,000 units of penicillin administered at three hour intervals, night and day, for sixty injections. The total amount of penicillin employed was 1,200,000 units. No other antisyphilitic medication has been used. All patients have been managed in a uniform manner, and it has not been necessary to decrease dosage or abandon the therapy in any instance. With three exceptions (acute arsenical intoxications) all the patients have displayed lesions characteristic of early syphilis (primary and/or secondary).

Herxheimer-like reactions, or therapeutic shock, of varying degrees of severity were observed during the first day of treatment in 86 patients. Ulcerations and cutaneous lesions manifested a tendency toward prompt recession. All uncomplicated ulcers were completely epithelized at the time of completion of treatment. No severe toxic reactions have been encountered. There were 2 instances of exfoliative dermatitis, 1 mild in character and of short duration, the second more severe

and requiring about three weeks for return to normal. The two patients had been treated with the same manufacturer's lot of material. As other irritative qualities were attributed to this particular product, the possibility of impurities being accountable for the skin reaction is present.

consideration of this phase the records of patients who have had in excess of seventy-five days satisfactory follow-up observation have been selected for scrutiny.

It may be well to state that the serologic routine which has been utilized in this study represents as complete a coverage as is practical; a total of seven

Because of the rapid disappearance of lesions the main reliance in evaluating the therapy has been placed on the serologic tests. On the reasonable assumption that the trend of the serologic reactions may be considered as an index to the progress of early syphilis in the human being, the treated patients may be placed into several rather well defined groupings. For a

accredited methods representing supersensitive and diagnostic flocculation methods, one diagnostic complement fixation technic and three methods with which the reagin content of each positive blood specimen has been quantitated.

On the basis of an arbitrary minimum of seventy-five days of satisfactory post-treatment observation, the

records of 52 patients become available for scrutiny. The average duration of observation is one hundred and thirty-five days.

Of this group of 52 patients, 6 with dark field positive lesions were in the seronegative phase of the disease at the time of treatment and passed through the observation period without positive findings being recorded.

tendency toward a return of the high titer reactions which were recorded at the time of treatment, and it is anticipated that complete reversal will be accomplished with the passage of time. However, there is no assurance of this contingency. There is the possibility that these patients eventually will be added to the favorably reacting groups.

A representative pattern of patients with secondary syphilis. High titer reactions show a consistent and progressive trend toward reversal to negative.

The records of 25 additional patients display positive serologic reactions in some or all test methods, with a reversal to negative findings during the observation period. The average time for reversal in this group was seventy days. Thus 31 patients may be considered as having responded in a favorable manner up to the present.

In 7 patients there has been a progressive decline in the serologic titer, and although complete reversal in all tests has not been accomplished there has not been a

In an additional group of 7 patients the records display an initial post-treatment trend toward seronegativity with subsequent unmistakable evidence of a return to the high titer reactions. These are considered to be instances of serologic relapse.

The remaining 7 patients have displayed serologic patterns which render difficult the making of a favorable or unfavorable classification at this time. Some pessimism is felt as to the effectiveness of the therapy in this group.

If the patients are grouped in accordance with the stage of the disease at the time of treatment, some items of potential interest become discernible. Of the 52 patients 30 may be classed as having dark field positive primary syphilis. Of this number 1 patient, previously mentioned, developed a clinical relapse nine

at this time. The remaining 25 patients are at this time clinically and serologically negative. Therefore there is a possibility of there being twenty-seven satisfactory responses.

Of the 22 patients who displayed evidence of secondary syphilis and who were well into the seropositivity

Pattern displayed by patient with early syphilis in which the therapy failed to influence the serologic picture.

months following treatment. A second patient displayed a well defined serorelapse after an initial favorable serologic trend for one hundred and twelve days after treatment. An additional member of the group experienced a clinical relapse after eighty-four days of practically unchanged high titer positive serologic reactions. Two patients who have displayed a progressive but protracted trend toward reversal cannot be readily classified

phase of the disease at the time of treatment, 11 have progressed to seronegativity or have displayed a consistently satisfactory trend in that direction. Four patients have shown a distinct tendency toward a recurrence of high titer reactions and must be classed as serologic relapses or as treatment failures. Two additional patients are looked on as probable failures and 5 are displaying a serologic trend which, although

favorable at the moment, displays a protracted decline which presages an unfavorable outcome.

The remaining tables represent serologic patterns which are considered to be representative of groups of patients.

COMMENT

The contrast which is displayed in the groups of treated patients rather indicates that (1) very early infections respond in the most favorable manner and (2) the increase in probable failures in patients with secondary syphilis indicates the need of a more vigorous therapy than that used in this study.

In evaluating the effectiveness of arsenic therapy in syphilis and of sulfonamide therapy in gonorrhea, it has been noted that a certain proportion of individuals fail to experience the same curative response which may be demonstrable in the majority of patients. A similar characteristic seems to be emerging in penicillin therapy of syphilis.

A majority of patients with early syphilis appear to respond to treatment in a satisfactory manner, as judged by the clinical course and the trend of the serologic reactions. A small group in the present series (7 definitely and 2 probably) appear to have derived a minimum of permanent benefit and must be considered as treatment failures.

In sulfonamide therapy of gonorrhea, failures of this type are classed as sulfonamide resistant and much has been written in regard to the drug resistance of strains of *Neisseria gonorrhoeae*. While accepting as possible that strain characteristics may play a role in determining the effectiveness of a therapy, it is felt that certain host factors are largely responsible for determining whether or not an agent, as penicillin, will be effective in infections which are amenable, as a rule, to treatment. It is felt that one of the most important problems in chemotherapy is a delineation of this essential factor and the development of means through which it may be favorably influenced.

In all the patients who have been classed as failures an observation period in excess of eighty-four days was required before an adverse decision as to treatment status was considered warranted. The data in these instances and in those which may occur among patients treated in the future will be scrutinized in an effort to determine a reliable basis for a more prompt decision predicated on clinical response and serologic pattern.

The making available of a pure or reasonably pure penicillin might effect a distinct change in the treatment picture both as to results produced and as to the duration of treatment, dosage and the interval between injections. Equally important will be the development of an assay method which gives assurance that the spirochetal activity of a product is consistently proportional to the antibacterial activity on which the present Oxford unit is based.

CONCLUSION

It is desired to recall that the disease syphilis is one which is characterized by chronicity, with long periods of latency and a distinct tendency to clinical and serologic recurrence. The evaluation of any therapy will require a prolonged trial utilizing a wide variety of treatment schedules and a carefully controlled follow-up system. The combined experience available at this time has served to illuminate only a few of the important aspects. The remainder must await the passage of time.

THE TREATMENT OF EARLY SYPHILIS WITH PENICILLIN

A PRELIMINARY REPORT OF 1,418 CASES

In December 1943 Mahoney, Arnold and Harris¹ reported briefly on the effect of penicillin in experimental syphilis of rabbits and in 4 human patients with seropositive primary syphilis. As a result of these observations and of further experimental studies carried out in the laboratories of Mahoney² and Eagle³ there was organized, about Sept. 1, 1943, under the general auspices of the Committee on Medical Research of the Office of Scientific Research and Development and under the specific direction of the Subcommittee on Venereal Diseases, National Research Council, a cooperative study of the effect of penicillin in syphilis in human beings. A Penicillin Panel was appointed by this subcommittee, with membership including the authors of this paper.⁴ Because of the special problems confronting the armed forces, particular emphasis has been laid on early syphilis and on neurosyphilis, though other forms of late syphilis have also been studied. The preliminary results obtained to date are here presented in two papers, this dealing with early syphilis; the other, with Stokes as spokesman for the group, with late syphilis.

The penicillin employed has been derived from Army, Navy, Public Health Service, and Office of Scientific Research and Development sources. Only the sodium salt has been employed in these studies. Penicillin allocated to the Office of Scientific Research and Development for research purposes has been distributed by the Committee on Chemotherapeutic and Other Agents, National Research Council, Dr. Chester Keefer, chairman. This committee has allocated gradually increasing amounts of the drug to the Subcommittee on Venereal Diseases, which in turn has apportioned it among those civilian clinics selected for participation in the study.

Early syphilis is at present under investigation in twenty-three clinics or research centers. These, with the names of the responsible investigators, are as follows: U. S. Army (Fort Bragg, North Carolina, Capt. William Leifer, Camp Howze, Texas, Major Franklin Grauer), U. S. Navy (Naval Medical Center, Bethesda, Md., Lieut. Comdr. E. C. Barksdale), United

The authors are members of the Penicillin Panel of the Subcommittee on Venereal Diseases, National Research Council.

The work described in this paper was done under several contracts recommended by the Committee on Medical Research of the Office of Scientific Research and Development.

Read in a panel discussion on "Penicillin in the Treatment of Syphilis" before the Section on Dermatology and Syphilology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

uniform manner. The immediate results of treatment were to be reported to the Penicillin Panel on specially devised forms (figs. 1 and 2), susceptible of coding, punch carding, and machine statistical analysis.

TABLE 1.—Four Treatment Schedules

Duration of Treatment	Interval Between Injections	Route of Administration	Single Dose	No. of Injections	Total Dose
7½ days	3 hours	Intramuscular	1,000 units	60	60,000 units
7½ days	3 hours	Intramuscular	5,000 units	60	300,000 units
7½ days	3 hours	Intramuscular	10,000 units	60	600,000 units
7½ days	3 hours	Intramuscular	20,000 units	60	1,200,000 units

On the basis of the very preliminary studies of Mahoney and his associates, there appeared to be five variables requiring study. These were (1) the route of administration, originally chosen¹ as intramuscular for the sake of slightly delayed absorption and excretion as compared to the intravenous route; (2) the interval between injections, at first selected¹ as every three hours day and night on the basis of known data as to the rate of absorption and excretion; (3) the duration of treatment, originally arbitrarily selected as eight days;¹ (4) the total dosage, again arbitrarily selected as 1,200,000 units,¹ and (5) possible combinations of penicillin with other drugs, e. g. mapharsen.

At the outset it was decided by the Penicillin Panel to hold the first three of these variables constant; i. e., all cases were to be treated by the intramuscular route every three hours day and night to a total of sixty injections given in seven and one-half days. The first effort was to be to define the minimum effective dose so given within this time period. Four treatment schedules were accordingly drawn up (table 1).

These covered a twenty fold dosage range up to and including the original maximum arbitrarily chosen by Mahoney and his co-workers. In addition there were originally planned (but subsequently temporarily dropped) two other groups, to test the combined effect of penicillin plus mapharsen. These two groups comprised a total penicillin dosage of 60,000 and 300,000 units respectively plus a total of 320 mg. of mapharsen given in eight divided doses of 40 mg. each daily for eight days. This mapharsen dosage was deliberately selected as a relatively safe and known subcurative dose from which a high rate of relapse might be expected.

Later, as material accumulated, the variable of time was brought under study, and three additional treatment groups were established with a total dosage of penicillin of 300,000, 600,000 and 1,200,000 units respectively given in thirty intramuscular injections every three hours day and night over a four day period. The latter groups have been so recently started as not

Moore and C. F. Mohr), Tulane University (Dr. R. V. Platou), Presbyterian Hospital, New York (Dr. A. B. Cannon), University of Virginia Hospital (Dr. D. C. Smith), New York Hospital (Dr. Walsh McDermott) and the Detroit Health Department (Dr. Loren Shaffer). This report is based on the work of these investigators and of many of their associates and assistants, too numerous to name.⁵

These clinics and centers agreed (1) to treat patients with early syphilis on assigned treatment schedules in an effort to define as promptly as possible the all important time-dose relationship and (2) to pool their results under the Penicillin Panel of the Subcommittee on Venereal Diseases. Only those patients in whom the diagnosis of early syphilis was indubitable, on the basis of actual demonstration of treponemes, were to be acceptable. All patients were to be originally examined and subsequently followed in as nearly as possible a

5. The statistical data have been prepared by Miss Gwendolyn Fletcher.

For the purposes of this report, the books of the Penicillin Panel have been temporarily closed as of May 25, 1944. To that date there had been received 1,587 case reports of early syphilis, of which 1,418 were suitable for analysis as to various points. Of these 177 had seronegative primary, 379 seropositive primary, 698 uncomplicated and 67 complicated⁶ early secondary syphilis and 97 various types of recurrent (usually previously treated) secondary syphilis. Of the patients 461 were white, 950 Negro and 7 of other races; 791 were male and 627 female, of whom 58 were pregnant at the time of treatment.

The preliminary nature of this report is indicated by table 2, in which the duration of follow-up after treatment is shown. The majority of patients have so far been observed for less than two months; only 113 of the entire number for four months or longer. This fact must be repeatedly emphasized as a matter of caution; the results here presented are subject to major revision after further observation. It is planned to report further information as it develops at three to six month intervals.

THE IMMEDIATE RESULTS OF TREATMENT

Disappearance Time of Treponema Pallidum from Open Lesions.—Data are available on this point from 663 cases treated with penicillin alone (excluding those cases treated with penicillin plus mapharsen).

Regardless of the single or total dose of penicillin, organisms have promptly disappeared from open lesions in every case within a range of six to sixty hours. At the two extremes of dosage, 1,000 and 40,000 units, the average disappearance time varied only from twenty-one to fourteen hours. Whether the apparent trend toward shortening of disappearance time is significant is open to question because of the varying intervals at which dark field examinations were done in the several clinics. Not shown in the table is the fact that the intravenous holds no advantage over the intramuscular route in this respect.

Healing of Lesions.—This is difficult to measure in statistical terms. There has been no observed instance of failure of lesions to heal, regardless of the single or total dose. With a total dosage of 60,000 units in eight days, healing is less prompt than with arsenical therapy; with larger total dosage, 300,000 units and up, it is as rapid as with standard chemotherapy or more so.

Serologic Response.—In figure 3 is shown the median blood serologic response,⁷ in terms of quantitative titer, of four groups of patients treated with penicillin alone (excluding those treated with penicillin plus mapharsen). Included are both seropositive primary and secondary syphilis. Regardless of the total dosage, whether 60,000, 300,000, 600,000 or 1,200,000 units, there is apparent a trend toward serologic reversal within a period of about twenty days after the start of treatment. Within the range of 300,000 to 1,200,000 units this trend is approximately uniform, regardless of

dosage; with 60,000 units it is a little slower and less pronounced. Parenthetically, this rate of serologic reversal is identical with that observed after arsenical chemotherapy, whether with an arsphenamine at weekly

patients with seronegative primary syphilis observed for nine or more weeks after the start of treatment. These are not broken down by total dosage since, regardless of the range of 60,000 to 1,200,000 units, the response was identical. In 28 patients the serologic test for syphilis, originally negative, remained so

TABLE 4.—Blood Serologic Response in Seronegative Primary Syphilis, Patients Followed More Than Nine Weeks from Start of Treatment, All Treatment Schedules Combined (June 1, 1944)

Cases Followed	Serologic Test for Syphilis		
	Negative, Remained Negative	Negative, Became Positive, Later Negative	Serologic Relapse
48	23	18	2

throughout the period of observation; in 18 it became temporarily positive, then reverted to negative, and in 2 only there was a subsequent serologic relapse. From the serologic standpoint, therefore, and during the very brief observation period so far available, the results may be said to be satisfactory in 95.8 per cent of the cases.

6. Complicated by asymptomatic neurosyphilis, syphilitic meningitis or ocular, osseous or visceral lesions.
7. This has been determined by a statistical device which assigns to the initial quantitative titer, regardless of the actual number of units, the numerical value of 100. All subsequent observations are expressed in terms of per cent of the original titer.

In seropositive early syphilis (combining seropositive primary and secondary syphilis) the results, now broken down by treatment schedule, are shown in table 5 (limited to patients observed for nine or more weeks after the start of treatment). Here there is a direct relationship between "satisfactory" and "unsatisfactory" immediate serologic results and total dosage of penicillin; the larger the dose, the better the result. The only and perhaps a major exception to this is in the group of patients who received 300,000 units of penicillin plus 320 mg. of mapharsen in seven and one-half days. This group shows as good initial results as were shown by patients receiving four times as much penicillin without mapharsen.

So far it is clear that the minimum effective dose of penicillin in early syphilis in man cannot be determined on the bases of disappearance time of surface organisms, healing of lesions or (except very roughly) serologic

relapse or apparently reinfection, has been classified as clinical relapse. Serologic relapse includes not only those who, originally seronegative or rendered so by treatment, subsequently became seropositive but also those who, still seropositive in low titer, subsequently develop high titer tests.⁸ An effort has been made to

Relapse After Penicillin Treatment.—In this material, relapse has been rigidly defined. Any subsequent clinical manifestation of the disease, whether obviously

observe all patients clinically and serologically at weekly intervals for the first two months, every two weeks for another two to three months and at least monthly thereafter.

The number of relapses reported in this paper is minimal and less than the number which have actually occurred. This is due to (1) an inevitable lag in reporting from the individual clinic to the Penicillin Panel and (2) delay in defining apparent serologic relapse on the basis of a single observation until confirmed by subsequent tests (for the sake of avoiding laboratory error).

The method of statistical reporting here adopted is recognizedly inaccurate in that the incidence of relapse is related to the total number of patients observed for a period of time greater than that of the earliest observed relapse. In the tables to follow all patients are included who were observed for thirty-eight days or longer after the start of treatment, since this was the shortest interval at which relapse was observed. The brief interval available for study prevents the adoption of the statistical method used by Eagle,⁹ which will, however, be utilized in later more definitive analyses. Preliminary rough test of this method of appraisal suggests that the eventual incidence of relapse will probably be from four to five times as great as that reported here. In table 6 is shown the incidence of relapse, clinical and serologic, in 92 patients with sero-

8. Not yet classified as relapse or "unsatisfactory result" are those patients whose serologic tests have shown no improvement. Twelve months after treatment will be allowed to elapse before such patients are classified as seroresistant.
9. Eagle, H.: The Treatment of Early and Latent Syphilis in Nine to Twelve Weeks with Triweekly Injections of Mapharsen: A Preliminary Analysis of the First 4,823 Cases, to be published

negative primary syphilis. The numbers, broken down by treatment schedule, are too small to be significant, though the total observed relapse rate, 3.2 per cent, is low.

Similar data for seropositive primary syphilis are shown in table 7 and for secondary syphilis in table 8.

TABLE 7.—Incidence of Relapse in Seropositive Primary Syphilis, Treated by Varying Schedules in Eight Days, Patients Observed for More Than Thirty-Eight Days (June 1, 1944)

These relate to patients treated with penicillin alone (excluding the combined penicillin with mapharsen groups). Here there is obvious a direct correlation between total dose and relapse incidence.

The data of tables 6, 7 and 8 are combined in table 9 for all patients with early syphilis; and here is added information concerning the patients treated with penicillin plus 320 mg. of mapharsen (two groups, 60,000 and 300,000 units respectively) and also concerning a small group of patients (25 in number) treated by the intravenous route before the present organized study was begun. In patients treated with penicillin by the intramuscular route the incidence of relapse, even in the brief observation period available, is in direct proportion to total dosage (nearly 30 per cent with 60,000 units, only 2 per cent with 1,200,000 units). In the small group who received large doses intravenously, ranging from 600,000 to 1,200,000 units, and whether by multiple injections or continuous drip, the observed relapses are five to six times as great as in patients treated with comparable doses by the intramuscular route, suggesting that the intravenous route not only holds no advantage over the intramuscular route but is actually less effective.

In table 10 the incidence of relapse is related to the stage of disease at the start of treatment in patients treated with penicillin alone (omitting the groups combined with mapharsen, among which only 1 relapse has so far occurred) and without regard to total dosage. In conformity with Eagle's report⁹ as to semi-intensive arsenotherapy, and in contrast to the older Cooperative Clinical Group and other data¹⁰ as to "standard" prolonged arsenical chemotherapy, there seems to be here a direct relationship between the stage of the disease at

the time of starting treatment and the incidence of relapse. The proportions in patients treated with penicillin alone are 3.2 per cent for seronegative primary, 5.0 per cent for seropositive primary and nearly 10 per cent for early secondary syphilis.

Table 11 shows the average and extreme intervals between the start of treatment and observed relapse. Here there is no direct correlation as to total dose. Relapses have occurred as early as thirty-eight days and as late as two hundred and ninety-four days after the start of treatment. Considering the short periods of observation so far available for all groups treated, further relapses in all may be confidently anticipated.

The Optimum Time-Dose Relationship for Penicillin in Early Syphilis.—The available data indicate that within the twentyfold dosage range employed in a period of seven and one-half days penicillin has a profound immediate effect in terms of disappearance of surface organisms, healing of lesions and serologic reversal. In seronegative primary syphilis no statements as to minimum effective dose are as yet justifiable. In seropositive primary and early secondary syphilis any dose less than 600,000 units in seven and one-half days is clearly ineffective. A total dose of 600,000 units provides a minimum relapse rate of nearly 5 per cent, of 1,200,000 units a rate of 2 per cent, within the short period for which such patients have so far been followed. The intravenous route appears to be less effective, even in large doses, than the intramuscular.

The possibility that even 1,200,000 units in a four to eight day period will prove to be inefficacious after further observation has led the Penicillin Panel to inaugurate the study of two additional treatment groups

TABLE 9.—Incidence of Relapse in All Types of Early Syphilis Treated by Varying Schedules, Patients Observed for More Than Thirty-Eight Days (June 1, 1944)

given a total of 2,400,000 units in thirty and sixty intramuscular injections in four and seven and one-half days respectively. These patients are being treated in the United States Army and eight selected United States Public Health Service rapid treatment centers.

The results obtained to date in the two small groups of patients given 60,000 and 300,000 units of penicillin respectively, in each case plus the known subcurative

10. Stokes, J. H., and others: Cooperative Clinical Studies in the Treatment of Syphilis: Early Syphilis, Ven. Dis. Inform. 13:165, 207 and 253, 1932.

total dose of 320 mg. of mapharsen in eight days, are worth emphasizing. In 94 such patients followed for thirty-eight days or more only one relapse has occurred. It is perhaps to be expected that certain patients with early syphilis will prove to be resistant to penicillin exactly as a relatively standard proportion of 5 to 15 per cent of patients has proved to be resistant to arsenic heavy metal chemotherapy. But, in view of what is already known concerning the probable modes of action of penicillin and of arsenic and bismuth in syphilis (considerations too lengthy for discussion here) it is possible that those patients resistant to penicillin will not be the same ones resistant to metal chemotherapy and that a combination of the two forms of treatment will eventually prove to be more effective than any method of use of either one alone.

It should also be emphasized that penicillin, as so far employed in early syphilis, is not suitable for mass application. Injections every three hours day and night over whatever period of time demand hospitalization and trained nursing or professional care. However available these may be for the armed forces, facilities are inadequate in civilian practice to meet the enormous demand. The eventual general use of the drug depends

on the development of methods which will permit its administration on an ambulatory basis.

As with arsenical chemotherapy, it is probable that the optimum time-dose relationship for the treatment of early syphilis in man with penicillin alone and its relative efficacy when administered alone or in combination with other forms of treatment will be guided by data from the experimental laboratory not as yet available but shortly to be expected.

In man, further immediate studies should be directed to (1) determination of the relative effectiveness of 1,200,000 units versus much larger doses in four and eight days respectively, (2) variation of the time interval between individual dosage within the range of three to twenty-four hours, (3) more exact definition of the merits of intravenous versus intramuscular administration and (4) an expansion of the combinations penicillin plus arsenic and penicillin plus bismuth.

Results of Treatment of Special Forms of Early Syphilis.—Thirteen patients with early syphilis in this series had positive spinal fluids before treatment (11 of them group 2, 2 group 3). Of these, the fluid abnormalities disappeared or improved under penicillin treatment alone in 10 within time period ranging from ten to fifty days; 3 were unimproved.

Acute Syphilitic Meningitis.—Ten patients with this complication of early syphilis have been treated, the majority with 1,200,000 units in seven and one-half days. Symptomatic relief has been dramatically prompt in all and, in the majority, spinal fluid abnormalities have disappeared or are rapidly improving.

Treatment Resistant Early Syphilis.—Eight patients, most of them with dark field positive psoriasiform syphilids, persisting in spite of or recurring during metal chemotherapy, have been treated with penicillin, with prompt healing in all and with subsequent serologic behavior similar to that of previously untreated early syphilis.

Infantile Congenital Syphilis.—Not included in the tabular presentations are some 20 infants with early congenital syphilis. The majority of them have been treated with a total dose of penicillin of 20,000 units per kilogram of body weight, corresponding to a total dose of 1,200,000 units in the adult. Their behavior in terms of symptomatic improvement and serologic response is analogous to that of early acquired syphilis in the adult.

The Outcome of Pregnancy.—Though 58 pregnant women with early syphilis have so far been treated, it is too early to speak of any results as to the outcome in the child.

REACTIONS TO PENICILLIN

Herxheimer Reactions.—Of 1,418 patients treated, 846 (59 per cent) have had Herxheimer reactions within the first twenty-four hours. This consists usually of fever alone (685 cases); in the others, exacerbation of secondary skin lesions with or without fever. The fever is usually mild (less than 102 F.), though in 174 cases (12 per cent) the febrile rise has been higher than this level. In no case has the reaction been alarming, nor has it interfered with subsequent treatment.

Other Reactions.—Only 59 patients (41 per cent of the total treated) have had other reactions attributable to penicillin. In 15 there were cutaneous eruptions (8 urticaria, 7 other types of skin rashes, none severe). Seven had mild gastrointestinal reactions, 33 secondary fever, 2 abscessed buttocks and 2 miscellaneous mild disturbances. In no case has penicillin treatment had to be suspended because of reactions from the drug.

SUMMARY

1. An organized study of the effect of penicillin in early syphilis is in progress in an effort to determine the optimum method of use of the drug. The results so far available are preliminary.

2. Penicillin has a profound immediate effect in early syphilis in terms of (a) disappearance of surface organisms from open lesions, (b) healing of lesions and (c) a trend toward serologic reversal.

3. These immediate effects are in general identical within a twentyfold dosage range of 60,000 to 1,200,000 units administered by the intramuscular route every three hours day and night to a total of sixty injections in seven and one-half days.

4. The same immediate effects are apparent within the dosage range of 300,000 to 1,200,000 units given by the intramuscular route every three hours day and night to a total of thirty injections in four days.

5. These immediate effects cannot be utilized to determine the optimum time-dose relationship, which, in man, depends on the incidence of relapse.

6. The incidence of relapse, when penicillin is administered alone, is in direct relationship to the total dosage given by the intramuscular route in a seven and one-half day period, greatest with 60,000 units and least with 1,200,000 units.

7. Relapse appears to be more frequent after intravenous than after intramuscular administration of comparable doses.

8. The lowest incidence of relapse—and the most favorable serologic response—was in small groups of patients treated with 60,000 and 300,000 units respectively of penicillin plus a known subcurative dose of mapharsen.

9. Penicillin has a favorable effect in early asymptomatic neurosyphilis, acute syphilitic meningitis, early syphilis treatment resistant to arsenic and bismuth and infantile congenital syphilis.

10. No opinion can be as yet expressed as to the effect of penicillin in the prevention of prenatal syphilis.

11. The optimum time-dose relationship of penicillin in early syphilis is not yet established. Certainly the minimum dose, especially in secondary syphilis, should not be less than 1,200,000 units; probably it should be more.

12. Herxheimer reactions after the penicillin treatment of early syphilis are frequent but not serious; other reactions, due to penicillin itself, are negligible.

13. Further avenues of study are suggested.

THE ACTION OF PENICILLIN IN LATE SYPHILIS

INCLUDING NEUROSYPHILIS, BENIGN LATE SYPHILIS
AND LATE CONGENITAL SYPHILIS:
PRELIMINARY REPORT

JOHN H. STOKES, M.D.

ST. LOUIS

These cases are drawn from eight clinics at present engaged in a study of the effect of penicillin on late syphilis, under the general auspices of the Committee on Medical Research of the office of Scientific Research and Development. These, with the names of the responsible investigators, are as follows: University of Pennsylvania (John H. Stokes, M.D.), Cornell University (Walsh McDermott, M.D.), Mayo Clinic (Paul A. O'Leary, M.D.), Boston Psychopathic Hospital (Harry P. Solomon, M.D.), University of Michigan (Udo J. Wile, M.D.), Bellevue Hospital (Evan Thomas, M.D.) and Johns Hopkins University (J. E. Moore, M.D.). Associated with each of them are various co-workers and assistants too numerous to mention here, but to whom due credit will subsequently be given.

Penicillin has distinctly beneficial serologic and clinical effects on neurosyphilis, including early and late manifestations, not excepting tabes and paresis, and including asymptomatic neurosyphilis. Its action on gummatous manifestations of skin, mucosae and bones

is so striking and complete that it seems unnecessary to collect further cases merely to demonstrate it as such. In ocular syphilis, simple inflammatory processes respond; later and more complicated lesions such as the optic neuritides and interstitial keratitis recover, relapse, present resistance and residues proportional to damage already done. This statement is probably true of visceral syphilis and of special localized processes and eighth nerve involvement.

These categorical statements are based on a material collected from 182 cases, observed for periods ranging from eight to two hundred and fourteen days after the institution of treatment. The preliminary conclusions are sharply limited by qualifications involving not only duration of observation and small numbers in individual breakdown items but by wide variation in time-dosage relationships and little uniformity as to time and type of test and recheck procedure. No precedents existing, each investigator groped his way into his problem. A considerable part of the material collected from nonuniform records was of such short observation and so "mixed" in therapeutic procedure that it furnished little evaluative worth. The distribution by source, duration of observation and diagnosis is given in table 1. Paresis, a crucial tester of therapeutic effect, heads the list (56 cases) and neurosyphilis totals 122 cases. Observation of sixty days or more was maintained in 44 Pennsylvania, 20 Johns Hopkins, 11 Mayo, 1 Bellevue, 5 New York Hospital and 1 Michigan case, a total of 82 cases.

Notwithstanding the limitations described, the material furnished the basis for demonstrating by both symptoms and laboratory tests (quantitative serologic, spinal fluid examination) the incontestable reality of the effect of penicillin treatment in syphilis. It permits an exploratory breakdown into grades of treatment effect as such, in relation to previous standard treatment; by at least two grades of intensity of penicillin treatment—low intensity (type A) 600,000 to 1,200,000 units of the sodium salt at 10,000 to 25,000 units intramuscularly every three to four hours and high intensity (type B) 2,400,000 to 4,000,000 units at 25,000 to 50,000 units intramuscularly every two to four hours. It was not possible from this material to estimate the difference in effect of hourly variations or unit dose variations, or of intravenous or intraspinal medication.

EFFECT OF PENICILLIN ON THE REAGIN TITER OF THE BLOOD

Irrespective of the system used and in all types of late (excluding latent) syphilis, penicillin causes improvement (reduction) of reagin titer in from about 50 to 60 per cent of 96 late cases in which such data were available (table 2). An initial Herxheimer-like rise or "provocative" effect is observable in about 20 per cent of late cases. Within the period of observation 10 per cent of late cases became completely negative.

In 5 cases of seroresistant syphilis, 1 became negative (low titer to start with) and 4 improved. Herxheimer effect occurred in 1.

In 32 cases of general paresis, disregarding treatment system employed, 16 were serologically improved, 2 reduced to negative.

EFFECT OF PENICILLIN ON THE SPINAL FLUID IN NEUROSYPHILIS

This furnishes probably the most graphic demonstration of the effect of penicillin, because of its multiple quantitative approach. Seven grades of change were

The authors are members of the Penicillin Panel of the Subcommittee on Venereal Diseases, National Research Council.

The work described in this paper was done under contract recommended by the Committee on Medical Research between the Office of Scientific Research and Development and several universities.

Read in a panel discussion on "Penicillin in the Treatment of Syphilis" before the Section on Dermatology and Syphilology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

considered: worse, no change and five grades of improvement as follows: grade 1, reduction in cell count or total protein; grade 2, reduction in both cell count and total protein; grade 3, reduction of cell count, total protein and intensity of colloidal test; grade 4,

Asympto- matic (40 cases)....	7	5	6	9	1	6	6
Total (107 cases)...	17	26	14	20	1	16	13

In a total of 107 cases which had had one or more spinal fluid examinations after completion of penicillin therapy, it appears that 78 cases showed some degree of improvement in spinal fluid findings, 43 slight and

35 definite. The commonest change is a reduction in cells and total protein, but grade 4 improvement is remarkably common, including all four items of the fluid examination. This response is, as would be expected, evident in a higher proportion (1/4) in asymptomatic neurosyphilis than in paresis (1/9). Some of the cases rated as "worse" are, we believe, to be regarded as Herxheimer or flare effects and would probably improve on longer observation. It is interesting that 4 asymptomatic cases accompanied by gummatous benign syphilis were among the 6 asymptomatic cases in which the condition became "worse."

In order to carry the specific touch of conviction to the doubter as to the effect of penicillin on the blood and spinal fluid, we reproduce here serial spinal fluid and blood observations of 6 patients, 3 with late con-

genital syphilis and 3 with acquired neurosyphilis. It is notable that these effects were secured with low intensity (type A) treatment in all but 1 case.

CASE HISTORIES

CASE 3 (Pennsylvania).—A man aged 38, with acquired syphilis. Primary optic atrophy in tabes, with euphoria, possible taboparesis. Fields (fig. 2) showed sector defect suggesting arachnoiditic or retrobulbar neuritic episode. Original spinal fluid, cells 122, Kolmer Wassermann reaction 4444, Pandey 4 plus, mastic 4442110000, improved to cells 29, Kolmer Wassermann reaction 0123, Pandey 3 plus, mastic 4432210000 by two Swift-Ellis treatments. After the first series of treatments with penicillin (table 4) the patient began to lose ground visually, with slight confusion and increased euphoria. The second series of treatments (table 5) resulted in definite improvement in fields, acuity and mental state.

CASE 5 (Pennsylvania).—A man aged 24 with congenital syphilis with typical stigmas, asymptomatic neurosyphilis, previously treated with forty arsenical and forty bismuth injections, was given the treatment outlined in table 6. He was retreated twenty-eight days later with the results shown in table 7.

CASE 11 (Pennsylvania).—A man aged 18 with congenital syphilis discovered at age 6 and treated with thirty neoarsphenamine injections a year for eleven years showed typical stigmas, neurologic signs, including Argyll Robertson pupils, anisocoria, partial ptosis of the left eyelid, weakness of the left seventh nerve and sluggish reflexes. He was given the treatment outlined in table 8. The ptosis disappeared under penicillin.

CASE 8 (Pennsylvania).—A woman aged 41 with acquired asymptomatic neurosyphilis discovered in blood donation, without symptoms or previous treatment, was given penicillin with the results shown in table 9.

CASE 29 (Pennsylvania).—A woman aged 29 with acquired neurosyphilis experienced sudden diminution of vision, advanced primary optic atrophy. Previous treatment, 1935-1939, consisted of eighteen arsphenamine and thirty-six bismuth injections. Treatment with penicillin (table 10) resulted in no improvement in fields or acuity: right eye 20/400, left eye 20/300.

CASE 50 (Pennsylvania).—A man aged 25 with congenital syphilis, showing typical stigmas and asymptomatic neurosyphilis, had been treated with sixty-two injections of neo-

arsphenamine and 102 injections of bismuth. Results of treatment with penicillin are shown in tables 11 and 12.

CASE 64 (Pennsylvania).—A man aged 37 with acquired syphilis, early paresis (?), showed sluggish pupils and lower cord reflexes and loss of memory. Previous treatment consisted of twenty-two mapharsen injections and nineteen bismuth injections.

SYMPTOMATIC RESULTS IN NEUROSYPHILIS

Since there is a well recognized disparity between symptomatic and serologic response in neurosyphilis, and the symptomatic often outweighs the serologic aspect in importance for the patient, symptomatic responses secured by penicillin in neurosyphilis were next examined. Here it is important to give warning of misinterpretations due to Herxheimer and possibly therapeutic paradoxical effects from overintense initial treatment. It is notable that some patients who did badly at the start improved later and that top notch symptomatic gains followed a low intensity system in some cases.

Penicillin also has a favorable effect in general paresis. Three groups were made up from the material (conceding the inadequacy from the psychiatric standpoint due to record deficiencies): simple demented paresis (grades 1, 2, 3); deteriorated paresis (grades 1, 2, 3); progressive paresis (galloping and so on) and symptomatic exacerbation suggesting Herxheimer effect. Improvement was graded 25, 50 and 75 and

100 per cent, the last representing practically complete restoration to normality.

Of 56 cases of paresis and taboparesis, 10 presented no adequate classification data. Of the 46 remaining cases 30 were classified as simple demented, of which

only 6 (20 per cent) failed to improve and 1 grew worse. Thirteen, or nearly half, improved 50 per cent or more, including 8 which improved 75 per cent and 1 restored symptomatically to normal. Ten cases improved only 25 per cent. As might be expected,

deteriorated cases (10) made less response, 1 improving 50 per cent, 2 75 per cent and 7 showing no change. The 1 patient with progressive or galloping paresis in Solomon's service died and 1 of Moore's simple demented patients died thirteen weeks after penicillin.

We know of no record of spontaneous remission under the good effects of hospitalization which can

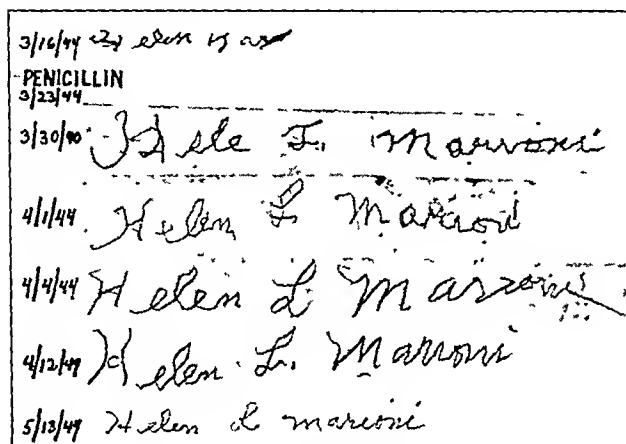

Fig. 1.—Improvement in handwriting of a simple demented parietic patient approximately six weeks after penicillin treatment. The signature before treatment is given above the word "penicillin" (courtesy of George D. Gammon, M.D.).

approach this. The transformations in orientation, speech, handwriting and encephalographic findings will be more fully presented from the University of Pennsylvania material in objective form by George D. Gammon, M.D., in a forthcoming paper. From the collected records, however, two brief summaries are given:

A white woman aged 34 with symptomatic paresis, grade 4 cerebrospinal fluid, could not write or do housework. She had auditory hallucinations, personality changes, disorientation, tremor of the tongue, hands and mouth, and slurred speech. On the second day of penicillin therapy she had a Herxheimer reaction with right-sided convulsions becoming generalized. After twenty-four hours penicillin was reinstituted at half dose to a total of 1,200,000 units without untoward effect. By the sixteenth day the patient was completely oriented, with memory, speech, tremor and electroencephalogram improved. In four months the patient was tremor free, speech and writing were normal (fig. 1), she was well oriented and hallucination free and was satisfactorily performing housework including marketing with points and driving a car. Clinical improvement was not accompanied by improvement in the spinal fluid.

A white man aged 42 with symptomatic paresis developed mispronouncing of words, garbled speech, uncertain gait, tremor of hands and difficulty in writing in August 1943, when a shell exploded near him. Forty-eight arm and hip injections were given. He became boastful, speech rambling and tremors were more pronounced; handwriting was worse and calculation poor. His condition was unimproved during hospitalization after 50,000 Oxford units per dose of penicillin to a total of 4,000,000 units. Clinical improvement occurred three weeks after penicillin with loss of tremors, improved handwriting and speech. He passed an examination as a pipe fitter. Improvement in the cerebrospinal fluid did not accompany clinical improvement. The neurologist considered him mentally improved but not to the original level.

Combining all types of clinically diagnosed paresis and taboparesis, exclusive of 10 patients treated with intraspinal or intravenous penicillin or malaria and thus totaling 46 cases, 15 failed to improve, 12 improved 25 per cent, 6 improved 50 per cent, 10 improved 75 per cent, 1 recovered and 2 died. Of 22 patients with tabes dorsalis, 14 presented data sufficient for interpretation, including 7 with primary optic atrophy and

3 with lightning pains of unusual severity plus 4 taboparetic patients with lightning pains who were grouped together with respect to this symptom. Of the 14 tabetic patients 3 improved to the extent of 50 per cent or more, and 2 of them with lightning pains were relieved completely. Eleven tabetic patients showed no change. Of the patients with primary optic atrophy none were made worse, and 1 whose visual fields are shown (fig. 2) improved slightly but definitely in both fields and visual acuity, with concomitant improvement in the spinal fluid. There is some question as to whether the sector defect in the left field is not a residue of a retrobulbar neuritic process. Of the total of 7 patients with lightning pains, 2 were completely relieved, 1 improved 50 per cent, 2 improved 25 per cent, 1 was unchanged and 1 became worse.

Of 16 patients with various forms of meningovascular neurosyphilis, 6 presented no data on clinical improvement. Of the remaining 10, clinical improvements of 75 per cent were observed in 2, 50 per cent in 2 and 25 per cent in 2, with 3 showing no change and 1 becoming worse.

It is of course difficult to evaluate symptomatology into which elements of the subjective and the influence of suggestion, rest, practice (as in eye and station and gait tests) enter. The intervention of trifling or routine medication (as in the eye, for example) with improvement found to have begun before penicillin, and hence

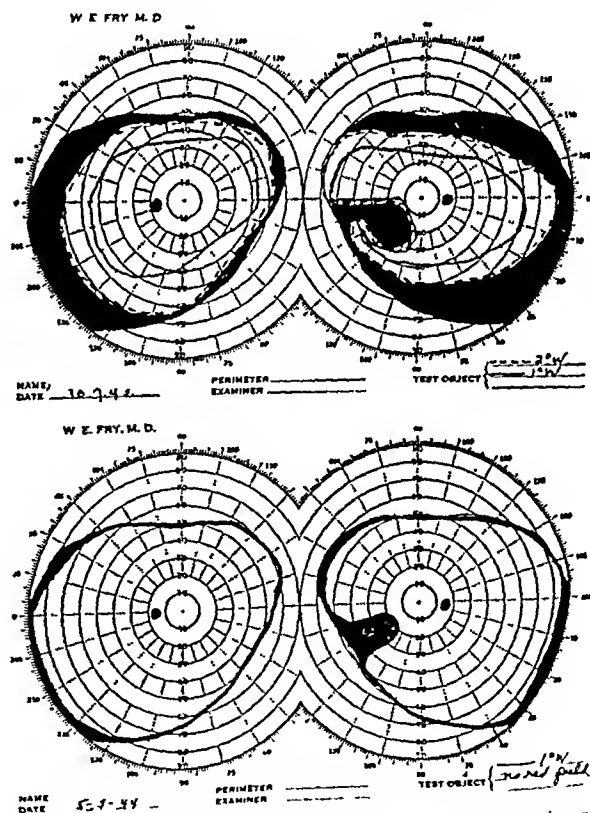

Fig. 2—Visual fields in case 3, Pennsylvania Penicillin Series, showing improvement with decrease in sector defect.

perhaps merely spontaneous or progressive, must be interpreted by long periods of observation. Symptomatology which is highly complex and of uncertain origin, such as lightning pains, in which the influence of the penicillin on other infective backgrounds may play a part, must be interpreted at this stage with reserve. There seems, however, to be a favorable trend in the

evidence pointing to genuine and indeed rapid good effect on the disease process, supported by such objective detail as handwriting change, encephalograms, disappearance of ptosis and of violent headache associated with meningitis. Coupled with the objective changes in the spinal fluid, such evidence would seem to deserve great weight. It is, however, unreasonable to expect penicillin to restore degenerations and replace neurons.

EFFECT OF TREATMENT SYSTEM

In this material the lack of system in dosage and time intervals reduced the number of cases per recognizable system below statistically usable levels, especially when viewed in relation to duration of observation. Some cases were jumbles of methods and had to be discarded. There were no blood level determinations, and in 3 Mayo Clinic cases spinal fluid penicillin determinations were repeatedly negative. Accordingly, only a study of type A versus type B treatment was attempted, type A representing 1,200,000 units or less, usually at 25,000 units every three to four hours, and type B 2,400,000 units to 4,000,000 units or more at 25,000 to 50,000 every two to four hours. Offhand there was no strik-

spinal fluids and completely achieve them on retreatment with a similar dosage, a steplike method of successive moderate applications of treatment as distinguished from a single massive session would seem to deserve further study. Pushing the patient over the hump, so to speak, to a partial self cure is a recognized principle in dealing with some aspects of late neurosyphilis.

Serologic response on the blood occurred in 45 per cent of the type A or smaller dose treatment cases, and in 43 per cent of the larger dose or type B cases. Longer observation periods for the type B cases would probably demonstrate a superior effect.

PENICILLIN RESPONSE IN RELATION TO INFLAMMATORY ACTIVITY

Using the cell count and the spinal fluid as a guide and rating 0 to 20 as low, 21 to 60 as medium and 61 and above as high cell counts, an attempt was made to see whether improvement was greater in cases showing a high cell count as an index of definite inflammatory activity in comparison to those showing low cell counts. With cell counts rated as high, improvement occurred

TABLE 14.—Effect on Spinal Fluid of Type A (Small Dose) Versus Type B (Larger Dose) Treatment

Type of Neurosyphilis	Grade of Response													
	Grade 1		Grade 2		Grade 3		Grade 4		Grade 5		No Change		Worse	
	A	B	A	B	A	B	A	B	A	B	A	B	A	B
Paresis and taboparesis.....	1	5	2	15	1	2	3	1	0	0	1	3	1	2
Tabes.....	1	3	0	1	0	1	2	2	0	0	0	5	1	0
Meningovascular.....	0	2	1	1	1	3	3	0	0	0	0	0	0	1
Asymptomatic.....	1	6	2	3	1	5	4	5	1	0	3	3	6	0
Grade totals.....	3	16	5	20	3	11	12	8	1	0	4	11	5*	3
Total type A.....	36		36		36		36		36		36		36	
Total type B.....		69		69		69		69		69		69		69

* Four of these patients had benign gummas healing under penicillin at a wholly inadequate dosage for neurosyphilis—less than 600,000 units. Grade 1 and 2 (slight) improvements occurred in 22 per cent of type A and 52 per cent of type B cases. Grades 3, 4 and 5 (definite) improvement occurred in 16 of 36 cases (44 per cent) on type A treatment and 19 of 69 cases (27.4 per cent) on type B treatment. Grades 2, 3, 4 and 5 improvement occurred in 60 per cent of the type A and 56 per cent of the type B cases. The periods of observation, however, were longer in the smaller dose treatment cases—e. g., paresis, over sixty days in type A; less than sixty days in all but 5 in type B cases.

ing difference recognizable between the effect of shorter time intervals or larger doses except the induction of Herxheimer reactions, which could be avoided by reduction in the dosage of the first twenty-four to forty-eight hours. The analysis of the case material on which treatment information was sufficiently complete for classification, comprising 105 cases, is given in tables 14 and 15.

It must be clearly recognized that such figures as these do not provide for trustworthy therapeutic inter-

pretations. It is particularly in point that the observation periods on the type B (larger dose) treated cases are shorter than those of type A and that a longer observation period may demonstrate a greater efficiency of larger dosage. On the other hand, it is also suggested that in late neurosyphilis good effects may be secured by less than the maximum dosage so far employed. If patients treated with 1,200,000 units in asymptomatic neurosyphilis can achieve almost normal

TABLE 15.—Degree of Cerebrospinal Fluid Improvement

Type of Treatment	Number of Cases	Slight, Grade 1, 2	Moderate to Definite, Grades 3, 4, 5	No Change or Worse
Type A	36	8 (22.2%)	16 (44.4%)	12 (33.3%)
Type B	69	35 (51.4%)	19 (27.9%)	14 (20.5%)

in 11 of 31 cases; with those rated as medium, in 13 of 28 cases; in those rated as low, in 7 of 45 cases. It appears that the proportion of improvement is highest in patients with medium and high cell counts in the order named and lowest in patients with low cell counts. If all cell counts above 20 are rated as high, improvement occurs in 24 of 59 cases in the higher cell count brackets (40.6 per cent) and in 7 of 45 in the low cell count bracket (15.5 per cent). Considering the small numbers of cases and the arbitrary division lines, the figures cannot be more than suggestive that, as has been previously indicated, a low cell count has a less favorable prognosis under penicillin treatment than a high cell count.

INFLUENCE OF PREVIOUS (ARSENIC, HEAVY METAL) TREATMENT ON PENICILLIN RESPONSE

An analysis of 100 cases of neurosyphilis with data on this matter yielded the results shown in table 16. The results in this case included grade 1 as well as grades 2, 3, 4 and 5. The type of previous treatment approximated the captions given, the first numeral representing arsenical, the second heavy metal injections.

Almost equally good results in the spinal fluid were achieved by penicillin after no previous treatment and intensive (40-80) routine treatment. There is at least no intimation that previous fever therapy prepared the

patients for striking penicillin results. The many qualifications on such an analysis with regard to selection, time of observation and so on must be recalled, but there is at least no strong evidence that in the aggregate previous standard treatment adds anything to the penicillin result.

PENICILLIN IN OTHER ASPECTS OF LATE SYPHILIS

Gummatous lesions of skin and bones (21 cases) respond so invariably and completely, with 13 results rated 100 per cent, 2 at 75 per cent, 4 questionable and only 2 failing of improvement (thirty-six and sixty-eight days), that little further clinical interest attaches to the group beyond speculation as to the part played by penicillin in clearing the secondary, usually hemolytic pyogenic infective invasion as distinguished from the syphilis as such. The control of destructive lesions of the palate and septum seems satisfactory. The failures include one suspected gumma of the orbit, diagnosis not established. The dosage required for symptomatic improvement ranges about 300,000 units, the time for healing from twelve to forty-six days. Carcinoma as a complication or a diagnosis must be watched for

TABLE 16.—*Spinal Fluid and Clinical Improvement in Neurosyphilis After Penicillin Treatment in Relation to Previous Treatment*

Type of Previous Treatment	Clinical Improvement Grade 1 and Over Occurred in:	Spinal Fluid Grades 1, 2, 3, 4, 6 Occurred in:
No treatment.....	16 of 32, or 50 per cent	28 of 32, or 87 per cent
Little treatment.....	9 of 23, or 39 per cent	16 of 23, or 69 per cent
20 arsenic, 20 heavy metal.	7 of 16, or 43 per cent	9 of 16, or 56 per cent
40 arsenic, 80 heavy metal.	5 of 16, or 30 per cent	13 of 16, or 81 per cent
Fever therapy.....	1 of 13, or 7 per cent	5 of 13, or 46 per cent

even if improvement occurs. Concomitant neurosyphilis was identified in 12 of the 21 cases. Serologic improvement (titer reduction) in the blood occurred in 14 of 21 cases.

The paradox of gummatous skin and bone lesions healing as the spinal fluid became "worse" (possible Herxheimer effect?) was noted in 3 of 10 cases.

LATE CONGENITAL SYPHILIS

The interest in this group centers on interstitial keratitis. The neurosyphilitic involvements were reviewed with neurosyphilis (see cases 5, 11 and 50). The complexity of interstitial keratitis and the eccentricities of its behavior are apparent under penicillin as under standard treatment. It was difficult to dissuade those in charge of some patients to withhold fever and other treatment if the patient did not immediately and strikingly improve. Patients with pronounced corneal and other ocular damage were included and too much was expected in the way of results. Of 14 cases 6 showed improvement, 3 of grade 4 on a scale of 1, 2, 3, 4, 1 of grade 3 and 2 of grade 2. Six showed no improvement and in 2 the condition was definitely worse. When improvement occurred it was apt to be dramatic. One patient previously given chemotherapy and fever energetically without result was given 1,200,000 units in eight days. He was relieved of photophobia by the third day and returned to work a week after penicillin for the first time in many months. He has remained well, improvement continuing up to the stage of stationary residue. Another improved grade 4 and one hundred and four days after penicillin flared and recovered again without further treatment. A persistently seronegative congenital syphilitic patient with characteristic stigmas made no response and in fact became worse

under 1,200,000 units. One of McDermott's patients, a fever failure, received a total of 4,845,000 units in two courses without results. Thomas secured improvement in a case on 4,000,000 units over twenty-five days, 20,000 units every three hours. Moore has excellent serial color photographs of a favorable case. One of his cases likewise improved on 3,970,000 units in twenty-one days, observed for one hundred and fifty-nine days.

OTHER EYE LESIONS

Two cases of optic neuritis on 2,000,000 and 3,000,000 units both showed improvement; O'Leary's case improved 100 per cent on retreatment. Two cases of iritis improved 100 per cent, but 1 relapsed and required an iridectomy for beginning glaucoma, after failing to respond to retreatment.

EIGHTH NERVE DEAFNESS

Eighth nerve deafness, beginning in a woman of 31 with undoubted stigmas of congenital infection, improved somewhat though not definitely on 1,200,000 units. There was a suggestion of Herxheimer-like drop in hearing at the outset followed by improvement, but the interpretations are complex. Two other cases, already far advanced, failed to improve.

MISCELLANEOUS CASES

A scattered group of cases, on which information is incomplete, includes bone-liver combinations, hepatosplenic complexes, seroresistance (Wassermann fastness) already discussed, Charcot hip and gangrenous balanitis in a syphilitic patient. The Charcot hip did not improve, and a suspected Charcot ankle is developing since penicillin. The gangrenous balanitis healed with the loss of less than a third of the corpus spongiosum on 300,000 units at about the rate to be expected of a late syphilid. The patient became seronegative. The livers of 2 patients undoubtedly enlarged (late cases) after treatment and the blood bilirubin increased in 1, then subsided.

REACTIONS TO PENICILLIN

Penicillin is not a reactionless drug. The disposition to pour it about like water in syphilis may lead to serious trouble, especially from therapeutic shock and possibly also from therapeutic paradoxical effects. The former is important under the usual rule that an active syphilitic process in a vital structure may be gravely and even fatally damaged by the impact of a large dose or series of doses at the start of treatment. Most Herxheimer effects, however, seem controllable by reduction in dosage for the first twenty-four to forty-eight hours of an eight day series without loss of ultimate effect. There is some question whether there are not delayed Herxheimer effects such as are suggested by spinal fluid and blood serologic curves and the initially unfavorable but ultimately favorable course of some lesions (eye, nervous system, for example).

Of 182 cases 43 (24 per cent) had reported reactions interpretable as Herxheimer or therapeutic shock effects. Of these 23 were fever, highest 105.5 F. The blood reagin titer increased definitely and then subsided in 7 cases. In 4 Pennsylvania cases symptoms interpreted as Herxheimer effects in the nervous system included transverse myelitic symptoms in 1 case, Jacksonian convulsions lasting twelve hours in another, exacerbation of lightning pains, mania and hallucinations.

Other reactions to penicillin included urticaria (2 cases) and 1 each of "allergic reaction," "id" reaction, burning of the skin, profuse sweating and phlebitis (intravenous injection). Two patients had sharp gastrointestinal reactions.

SUMMARY

From a material of 182 cases of late syphilis preponderantly neurosyphilis (122 cases) and including benign gummatous syphilis, ocular and other forms of syphilis and late congenital syphilis, observed from eight to two hundred and fourteen days after the penicillin therapy was begun on a wide range of time-dosage schedules, the following tentative observations are summarized:

1. The lesions of benign gummatous syphilis of skin and bones heal under a dosage of approximately 300,000 units in twelve to forty-six days.

2. Irrespective of the system used, and in all types of syphilis, penicillin causes reduction of syphilitic reagin titer in the blood in from 50 to 60 per cent of late cases. An initial "Herxheimer"-like or provocative rise is observed in about 20 per cent of cases. Only 5 sero-resistant cases were treated, 1 made negative, 4 improved.

3. The abnormal spinal fluid in neurosyphilis is improved in 74 per cent to some degree, definitely in 33 per cent. The commonest change is a drop in cell count and total protein (grade 2 improvement on a scale of 5) occurring in 67 per cent of cases. One spinal fluid was rendered normal within the observation period. All four fluid findings improved in 25 per cent of the cases of asymptomatic neurosyphilis, 10 per cent in paresis and taboparesis.

4. Symptoms improved in neurosyphilis as follows: Simple demented paresis: In 30 cases on which data were adequate for classification, 80 per cent improved to some degree; nearly half improved 50 per cent or more, including 8 who improved 75 per cent and 1 restored to normal. Deteriorated paresis: Two of 10 improved 75 per cent, 1 50 per cent, 7 no change. Tabes dorsalis: One fifth of 14 cases improved 50 per cent or more. Of 7 with lightning pains, 2 were completely relieved, 1 improved 50 per cent, 2 improved 25 per cent, 1 unchanged and 1 worse. Of 7 cases of primary (?) optic atrophy, mostly advanced none were made worse, 1 improved. In meningovascular neurosyphilis 40 per cent improved 50 to 75 per cent.

5. Two attempts at statistical evaluation were made: One, of the influences of smaller dose as contrasted with larger dose treatment and the other, of the response under penicillin of spinal fluids with low as contrasted with relatively high cell counts, because of small numbers of cases and unavoidable disparities in observation period, cannot be accepted as beyond challenge. They suggest respectively that in late syphilis, especially neurosyphilis, smaller doses, if not grossly inadequate, have good effects which may perhaps be improved by repetition, as compared with the effects of initial larger dosage, the effect being due perhaps to stimulation or utilization of the patient's resistance and defensive responses. The figures on response in relation to cell count suggest that moderate and high cell count cases tend to react somewhat better than cases giving low cell counts.

6. Previous treatment for syphilis by older methods in neurosyphilis, including fever therapy, does not appear to prepare patients for superior results with penicillin.

7. In late congenital syphilis, interstitial keratitis presents rather equivocal though at times dramatically favorable results, not as yet interpretable in relation to a time-dosage system. Of 14 cases 6 improved, 3 to 100 per cent, 1 to 75 per cent, 2 to 50 per cent. Two were made definitely worse.

8. Optic neuritis included 2 cases, both improved, the second 100 per cent on retreatment. Two cases of iritis improved 100 per cent at the start, but 1 relapsed and did not respond to retreatment (glaucoma).

9. Two cases of eighth nerve deafness gave equivocal results.

10. Of miscellaneous cases, Charcot joint was unaffected (a new one developing); gangrenous balanitis was cured by low dosage.

11. Therapeutic shock (Herxheimer) effects are undoubted, may be serious in late syphilis and should be guarded against by reduced dosage during the first twenty-four to forty-eight hours. Severe cerebral and cord symptoms may develop in neurosyphilis.

Reactions to penicillin as such are few and not serious, urticaria, itching, allergic skin reactions and a sharp gastrointestinal reaction following the course.

12. It is suggested that, because of the great difficulty in developing uniform records for statistical or punch machine evaluation in late syphilis, further investigation of its behavior under penicillin therapy be committed to individual competent investigators who can apply the principles of uniformity of treatment and record evaluation simultaneously with appropriate individualization of the particular case. The durability of the good effects thus far observed, the possibility of complications from induced allergic response and disturbance of the immunity balance of the individual in latent and late syphilis remain to be explored by larger experience and longer periods of observation.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. MAHONEY, ARNOLD AND STERNER AND MESSRS. HARRIS AND ZWALLY, OF DRS. MOORE AND MAHONEY, COMMANDER SCHWARTZ, LIEUTENANT COLONEL STERNBERG AND DR. WOOD, AND OF DR. STOKES, LIEUTENANT COLONEL STERNBERG, COMMANDER SCHWARTZ AND DRS. MAHONEY, MOORE AND WOOD

LIEUTENANT COMMANDER E. E. BARKSDALE, MC-V(S), U.S.N.R.: As of June 1, 1944 we have treated 161 cases of syphilis with penicillin. Twenty-nine were seronegative, dark field positive, primary syphilis, clinically cured and are still seronegative to date. Eighty were seropositive, dark field positive primaries. Of this group 2 relapsed within approximately three weeks after treatment was started. The lesions recurred in the same location and again became dark field positive. One of this group healed, becoming seronegative, and then acquired a new infection with a dark field positive chancre in a different location from the previous one. We have treated 31 cases of secondary syphilis. All the cases were treated on a dosage of 1.2 million units intramuscularly, i. e. 20,000 units every three hours for sixty injections. By determining quantitative blood penicillin levels on these patients treated with intramuscular injections every three hours, we found that it was impossible to maintain a constant penicillin level, and indeed for one third of the time there was no penicillin detected in the blood by the test used. This made us think that the continuous intravenous drip method might be the procedure of choice. To date we have treated 11 cases of syphilis by this method, giving a total of 2,080,000 units of penicillin in nine days. With this we were able to maintain a more or less constant blood penicillin level approximately ten times higher than that which could be obtained by the intramuscular route. We have had no

relapses, no central nervous system involvement and no case has retained a positive serologic reaction as yet beyond the fourteenth week. To date we have treated 7 cases of syphilis with the usual routine of fever therapy but substituting for mapharsen 60,000 units of penicillin intravenously each time they were in the fever cabinet. In addition and over the same period of time we gave each patient 20,000 units of penicillin intramuscularly every three hours until a total of $3\frac{1}{2}$ to 4 million units had been given. It is our impression that this method is superior to the one which we had formerly used. I am of the opinion at the present time that penicillin is the best drug we have ever had for the treatment of syphilis. I think that it is possible that the intravenous method of administration may be superior. We have had 1 case of primary syphilis treated intramuscularly with 1.2 million units, which ended fatally ten days after the completion of treatment, of a subdural hemorrhage which was not related to either the syphilis or the treatment. Pathologic examination of body tissues with special stains failed to reveal any spirochetes. At autopsy therefore this 1 case within ten days after treatment gave no pathologic evidence of syphilis.

CAPTAIN WILLIAM LEIFER, M. C., A. U. S.: The experience at Fort Bragg now comprises 116 patients treated for syphilis with penicillin. One hundred received 1,200,000 units and 16 received 2,400,000 units in seven and one-half days (technic sixty consecutive intramuscular injections of 20,000 or 40,000 units at three hour intervals). Reactions were infrequent and inconsequential; there were 3 instances of urticaria, 1 of erythema multiforme, 2 of generalized pruritus and 7 of herpes simplex. Focal and systemic Herxheimer reactions appeared on the first day of treatment in 87 per cent of the patients. Only those who received 1,200,000 units and who have been followed at least three months are being reported. Ten patients began treatment in the seronegative primary phase and 12 in the seropositive primary phase. Four have been observed over six months, of whom 3 are seronegative, while the fourth has a doubtful Kahn reaction. All 4 had negative spinal fluids at six months. The remaining 18 patients have been followed from three to six months, and all but 1 are seronegative. Thus, 20 of the 22 cases of primary syphilis have achieved or maintained seronegativity. Twenty-five patients began treatment in the secondary stage of syphilis. Two have exceeded six months of observation; 1 is seronegative and the other has a doubtful Kahn reaction. Both had negative spinal fluids at six months. The remaining 23 patients have been followed between three and six months; of these, 11 are seronegative, 9 still have some degree of positivity of the blood and 3 are definitive failures. Two failures appeared as neurologic relapses (1 with monoplegia, the other with acute syphilitic meningitis) with strongly positive spinal fluid; the spinal fluid had been negative in both of these immediately before administration of penicillin. The third failure was a cutaneous and serologic relapse. Thus, of 25 cases of secondary syphilis 12 are seronegative, 10 are still seropositive and 3 are outright failures. It would seem best to use higher doses than might now appear necessary in the treatment of syphilis. The future may reveal the need not only for an increase dosage but also for prolongation of the treatment period beyond the present seven and one-half days. Thus far the results have been extremely encouraging, but mass treatment of syphilis with penicillin should be delayed until the optimal treatment schedule is determined.

COMMANDER FRANK A. ELLIS, Corpus Christi, Texas: I should like to give you some of the highlights of the experience with penicillin starting in New Zealand in Wellington and extending up to Corpus Christi. An enlisted man with acute infectious jaundice, after being in the hospital five days, developed an acute gonococcal urethritis. His icterus index was 45, and we gave him penicillin; it cured his gonorrhea, and his icterus index was brought down to 0.5. Penicillin might cure acute jaundice or acute infectious jaundice, as we designate it in the Navy. Our results in probably 450 cases of acute gonococcal urethritis have been 100 per cent effective, with this exception: We had 2 cases in which acute epididymitis developed three days after administration of 100,000 units of penicillin. On those we immediately repeated the therapy and gave them 200,000 units until the smears, urine culture and prostatic

cultures were negative. My impression is that it certainly shortens the course of acute epididymitis. Our results have been most disappointing in penicillin therapy for nonspecific urethritis. With syphilis I have had no experience whatever except this, that I want to caution you about intraurethral chancre being masked in acute gonorrhea. If patients are given 100,000 units, the dosage will be inadequate.

COLONEL UDO J. WILF, U. S. P. H. S.: It is too much to expect of penicillin at this time more than has been graphically told by the authors. We should accept these facts with the possibility that in time the organisms may elaborate for themselves a certain degree of resistance to penicillin. When we can speak in terms of thousands instead of terms of hundreds, we may have more relapses and more recurrences and possibly more reactions. It is, however, a great relief to those of us who have for years felt that we were using dangerous drugs in the treatment of syphilis to find something at least that departs from heavy metals that gives a high index of therapeutic effectiveness and apparently a low toxicity.

DR. JOSEPH E. MOORE, Baltimore: I close on the same restrained note of optimism which has been voiced to you here. I don't think that penicillin is ready for mass application. I do feel that our attitude ought to be one of hopefulness, but with complete understanding that we are still in the process of learning how to use the drug. We don't know yet, and it is going to be some time before we are sure.

SOME HARMFUL EFFECTS OF RECUMBENCY IN THE TREATMENT OF HEART DISEASE

SAMUEL A. LEVINE, M.D.
BOSTON

Rest of the affected part is a fundamental form of treatment in many diseases. When a bone is fractured, splints are applied and the involved parts are immobilized. This not only diminishes pain but speeds repair and healing. When a lung is actively affected with tuberculosis, attempts are made to diminish the movements of the diseased lung. The phrenic nerve may be sectioned, pneumothorax produced or thoracoplasty performed, the purpose of these procedures being to rest the affected organ. In a similar way when the heart is diseased, rest in bed has been urged as a means of diminishing its work. Not so long ago the relative value of rest and exercise was much debated and was summarized by Pratt,¹ who strongly advocated prolonged rest in bed for heart failure. At present all students and physicians have been forcefully impressed with the great importance of rest in bed, although in practice one finds great variations in the degree to which the principle is applied. Under similar circumstances one physician may keep a patient in bed a few days, another a few weeks and a third a few months. What should be our guide and what are the hazards, if any, of strict bed rest?

At the outset, a clear distinction must be drawn between the function and dynamics of the heart and the conditions that obtain in other organs. One important peculiarity of the heart is that it has two sides, right and left, and that serious difficulties may ensue if an imbalance develops between the two. If the right ventricle expels one drop of blood less than the left ventricle, within a few hours there will be increased

From the Medical Clinic of the Peter Bent Brigham Hospital and the Department of Medicine, Harvard Medical School.
Read at the dedication of the National Institute of Cardiology, Mexico City, Mexico, April 20, 1944.

venous pressure and pronounced engorgement of the liver. Contrariwise, if the right ventricle expels one drop more than the left ventricle there will result pronounced pulmonary edema. In each instance 250 to 500 cc. of blood would be trapped either in the systemic venous system or in the pulmonary circuit. Similarly it follows that, when there is definite pulmonary congestion, those measures that reduce the return flow to the right side of the heart, and therefore the output of the right ventricle, relieve pulmonary congestion and help to restore the balance between the two sides. We are all familiar with the beneficial effects of phlebotomy or the application of tourniquets to the extremities in this regard.

With the foregoing considerations in mind it is well to analyze the effects of putting a cardiac patient to bed. In general, rest obtained in this way decreases the total bodily demands or basal metabolism, slows the heart rate and may lower the blood pressure. All this decreases the work of the heart. The one factor that has been overlooked, for the most part, is that the effect of recumbency is also to encourage venous return. As the lower part of the legs remain elevated and approximate the level of the right side of the heart, tissue edema more readily disappears through the lymphatics, capillaries and venules. The result of this mechanism is to increase rather than to decrease the work of the right side of the heart. When this effect is considerable and the left ventricle is so weak that it cannot keep pace with the increased output of the right ventricle, during the hours or days of recumbency, pulmonary congestion and resultant breathlessness may actually increase. In other words bed rest, for a while, may impose greater rather than less work on the heart.

All physicians are familiar with the clinical events that take place during an acute attack of nocturnal cardiac dyspnea or so-called cardiac asthma. A patient, generally with hypertension, coronary or aortic valvular disease goes to bed feeling fairly well and about 2 o'clock in the morning is awakened with breathlessness, suffocation and possibly cough and wheezing. He generally jumps out of bed, walks around the floor in his agitation, goes to a window for air or sits up in bed with his feet hanging down. In fifteen minutes or a half hour the attack may be over and he falls back to sleep. Some find that they can sleep the remainder of the night only if they sit in a chair. The surprising thing is that, although our patients have long been aware of the harmful effects of the bed and have dreaded the nights, we as physicians would generally insist that they be put on a strict bed regimen. Many of our patients would emphatically state that they felt quite well while they were up and about, some of them even being able to do quite a bit of work during the day but had all their trouble in bed. With equal persuasion we would maintain that they had to go to bed.

It is true, however, that in most cases when we put such patients to bed no harm resulted. In fact, they generally improved. Often the nocturnal dyspnea disappeared and both the patients and the physician became convinced that bed rest was valuable. Nevertheless a closer analysis will reveal, I believe, that some temporary ill effects were produced but that in most instances the various methods of treatment employed were effective enough to counterbalance and mask them. Only when the entire program of treatment is ineffective do we see gross evidence of the deleterious results that

are produced by bed rest. I recall, as many physicians will on close reflection, frequent instances in which shortly after ordering an ambulatory cardiac patient to bed pulmonary rales and hydrothorax, previously absent, quickly appeared. Such a patient may have complained of nocturnal dyspnea and shown no peripheral edema or slight pitting of the legs. The lung bases were clear of rales at that time. Ordinarily with complete bed rest the nights are made comfortable by the use of hypodermics of morphine until the effects of digitalis, diuretics, diet, phlebotomy and other measures have improved the situation so that pulmonary congestion clears and breathing becomes normal. But in the type of case mentioned, for one reason or another the progress is down hill because the customary treatment is not effective enough to undo the harm done by the recumbent posture. Such a patient often shows complete disappearance of peripheral edema but now needs a thoracentesis for a right hydrothorax. Even if no pitting is apparent we must realize that patients may have several liters of latent edema without pitting. It also must be borne in mind that fluid in the legs may be unsightly but does comparatively little harm, whereas fluid in the lungs is a dangerous handicap.

Another illustration of the shift of fluid from the lower to the higher portions of the body in decompensated cardiac patients is the disappearance of pitting edema of the ankles while extensive edema of the lower part of the back develops. Physicians often seem pleased that the ankles have returned to normal size in their cardiac patients who are confined to bed and overlook the fact that the same fluid is still within the body, only now is distributed in its upper portions.

One might ask what evidence there is that it is the bed rest that causes these changes. First, it is the experience of our patients (just cited), who often are our best teachers. Then it is the clinical detection of increasing signs of pulmonary congestion in some cases (while the peripheral signs decrease) coming during the first few days after bed rest has been instituted. Finally, certain laboratory data afford convincing proof to support these clinical impressions. It is known² that normally there is a decrease in the total lung volume of over 300 cc. and a decrease in the vital capacity of the lungs of about 200 cc. in the recumbent position. These changes may possibly be greater in patients already suffering from congestive failure. Several years ago³ I made a few casual observations on the vital capacity of the lung and the velocity of blood flow just before putting cardiac patients to bed and one or two days later. The former was found to decrease slightly and the latter to slow before real improvement began. More recently a systematic study was made by Perera and Berliner⁴ on the effect of posture on the dynamics of the circulation in normal individuals and in patients with paroxysmal nocturnal dyspnea. They found that the assumption of the horizontal position caused a decrease in serum concentration and slight increase in venous pressure in both groups. The serum protein was also found to rise toward the normal levels in patients about fifteen minutes after the attacks of dyspnea were over. The

4. Perera, G. A., and Berliner, R. W. The Relation of Postural Hemodilation to Paroxysmal Dyspnea, *J. Clin. Investigation* 22: 25, 1943.

only reasonable interpretation that can be made from these observations, and the conclusion drawn by these authors, is that with recumbency hemodilution and increased blood volume occur as a result of the flow of fluid from the tissue spaces into the blood stream. This obviously is deleterious to cardiac patients, and when there is a tendency to dyspnea from left ventricular weakness or from serious mechanical obstruction of mitral stenosis serious pulmonary edema may result.

An increase in blood volume is one of the most constant findings in congestive heart failure, and effective treatment is always concomitant with a decrease of blood volume toward normal. The observations cited show that recumbency produces, at least temporarily, exactly the effect that is undesirable by increasing the total volume of blood and as a result the work of the heart. It is clear therefore that, although the fundamental principle that rest is beneficial for the heart remains undisputed, the recumbent position in some cardiac patients may actually increase the work of the heart. To be sure, this effect is often temporary; for when sufficient improvement has occurred the left ventricle is able to expel its quota of blood or the right ventricle no longer delivers an excess into the pulmonary circuit and a proper balance has been established. From then on rest in bed does accomplish its purpose in diminishing the total work of the heart.

There are other difficulties that may follow prolonged bed rest both in cardiac and in noncardiac patients. In some elderly men urinary retention from an atonic bladder and prostatic obstruction may first develop after confinement to bed. This may necessitate catheterization with the occasional development of infection and its complications. Many others may develop hypostatic pneumonia, which used to be so often fatal to chronic cardiac patients.

What we have learned to be much more important is the frequent occurrence of thrombophlebitis of the legs with subsequent pulmonary embolism. The medical profession has only in the past few years become aware of the extent and seriousness of this problem. Williams and Rainey⁵ even suggested that the initial period of complete bed rest should be reduced, because in a large number of their cardiac patients pulmonary infarction and pneumonia were found to be the cause of death.

In Boston, in large measure as a result of the clinical studies of diseases of the veins by John Homans⁶ and the pioneer work on acute cor pulmonale by P. D. White and his associates,⁷ we are recognizing more and more cases of pulmonary embolism. As we all know, this is a common cause of death following operations in any surgical clinic. It is equally frequent in the medical wards in hospitals, especially in patients confined to bed for any appreciable time. Immobility of the legs, abdominal distention with its inevitable pressure on the iliac veins, and the sluggishness of the circulation in cardiac patients all result in slowing of the blood flow through the legs, which is conducive to venous thrombosis. This is particularly true of very obese and orthopneic individuals, for in a sitting position there is added constriction of the pelvic veins.

When cardiac patients are examined post mortem and pulmonary emboli or pulmonary infarction are

found, one is too ready to explain them on the basis of emboli from the right side of the heart or as a result of local thrombosis of the pulmonary vessels. Only a careful search of the veins of the legs or pelvis will reveal the great frequency of thrombosis, which proves to be the actual origin of these pulmonary complications. This entire situation is serious and in many cases the medical profession is to blame. I know I have been directly responsible for needless fatalities from pulmonary embolism in patients who would have done well had I not put them to bed. As a corollary to the foregoing we should be quick to detect any phlebitis of the leg, especially the deep type of thrombophlebitis. This often starts in the calf and is not manifested by gross swelling of the leg but rather by early pain in the calf on dorsiflexion of the foot. Certainly, if a patient with such phlebitis has one pulmonary embolism or some obscure sudden respiratory episode, ligation of the vein should be performed immediately. In fact, my fear of a fatal pulmonary embolism has become so great that I advise immediate femoral vein ligation just as soon as a deep phlebitis is recognized.

The following case reports will illustrate some of the preceding points:

CASE 1.—A shopkeeper aged 58 had a typical attack of acute coronary thrombosis April 10, 1937. Severe and increasing breathlessness developed during the following three weeks. At this time (May 3, 1937) I first saw him and found him to be irrational and considerably orthopneic, with Cheyne-Stokes breathing. The lungs were full of rales, but there was no pitting edema of the legs. The heart sounds were distant, regular and rapid. He had been in bed under an oxygen tent most of the time. I advised omitting the various medications he was receiving, such as aminophylline, digitalis and caffeine, and had him placed in a chair with his feet hanging down. Within a few hours his condition began to improve. Two days later he showed edema of the legs, but the orthopnea was practically gone and he was rational. He then received digitalis and mercupurin, had a satisfactory diuresis and gradually recovered compensation. He was still ambulatory and in fairly good health three years later. The turning point in this patient's condition occurred directly after getting him out of bed into a chair. The edema lessened in the lungs as it increased in the legs.

CASE 2.—G. H., a business executive aged 66, seen in my office Feb. 1, 1934, had been slightly short of breath for a few years but carried on his work fairly well. Since August 1933 he had frequent smothering attacks, waking him up from sleep. He would have to sit up in bed and get into a chair for relief. During the day, while he was up and about, he was comfortable.

Physical examination showed considerable cardiac enlargement, a grade 2 aortic systolic murmur, a definite gallop rhythm and a definite pulsus alternans. The rhythm was regular, with a rare extrasystole. The breath sounds were much decreased, the liver was slightly enlarged and there was moderate pitting edema of the legs.

He was put on complete bed rest in the Peter Bent Brigham Hospital and assured that he would be made comfortable, though he insisted that he feared the bed. The first few nights were in fact quite comfortable, because he was given hypodermic injections of morphine, which he had never received before. He was also started on digitalis therapy by mouth. Two days after admission, edema of the legs had entirely disappeared; but now a right hydrothorax was present, which was not there when I first put him to bed. The breathing became more labored and of the Cheyne-Stokes type. A right thoracentesis was performed, removing 1,200 cc. of clear fluid on the fourth day; and from then on, with the help of mercurial diuretics, his condition improved. As compensation was regained, the basal systolic murmur became more prominent, an aortic systolic thrill was felt, and x-ray examination showed definite calcific aortic stenosis. After several weeks he became ambulatory and free from dyspnea and edema.

7. McGinn, S., and White, P. D.: Acute Cor Pulmonale Resulting from Pulmonary Embolism: Its Clinical Recognition, *J. A. M. A.* 104: 1473 (April 27) 1935.

This is a striking instance of a shift of fluid from the periphery to the chest on putting a cardiac patient to bed. The patient did become worse as a result of the position in bed and showed improvement only when active cardiac therapy caught up with and undid the harm done by recumbency. This might have been avoided if he had been treated in a more upright position or in a chair during the first week.

CASE 3.—E. G. B., a housewife aged 58, came to my office Nov. 27, 1936 complaining of weakness, dizzy spells and inability to lie flat because of shortness of breath and choking feelings. These symptoms began only a few months before she was first seen.

The patient was obese, weighed 98 Kg. and was 61 inches (155 cm.) in height. The heart was entirely normal, the lungs showed a few basal rales, the abdomen was prominent but otherwise not remarkable, and there was slight puffiness of the legs. The blood pressure was 180/105. The urine was normal. The vital capacity of the lungs was much decreased (1,400 cc.). The electrocardiograms were normal.

She was sent to the hospital with a diagnosis of obesity and slight hypertensive heart disease. She was put on a 600 calory diet, kept in bed and given digitalis. She lost about 6 Kg., though there was no diuresis. There was no change in her clinical condition and there was never any evidence of phlebitis of the legs. On December 26 she suddenly developed severe dyspnea. This was erroneously regarded as left ventricular failure, and digitalis, which had previously been omitted, was reinstituted. She remained dyspneic thereafter and died suddenly on Jan. 1, 1937.

Postmortem examination showed some cardiac hypertrophy and dilatation but no cardiac thrombi or significant coronary artery disease. There were numerous pulmonary infarcts and large adherent antemortem clots in each pulmonary artery. A large fresh red friable thrombus was present in the right common iliac vein.

This is an instance of acute fatal pulmonary embolism coming during the course of bed care in an obese hypertensive woman. It seems more than reasonable that this would not have occurred if she had remained ambulatory. Both the immobility of the legs during her period in bed and the pressure of the large abdomen on the pelvic veins, which was accentuated by the sitting position in bed, must have been precipitating factors in the production of thrombosis of the veins of the legs, which led to the pulmonary embolism.

CASE 4.—D. W., a hotel manager aged 52, entered the Peter Bent Brigham Hospital Feb. 10, 1944 complaining of frequent attacks of pain in the midchest. Beginning in February 1941 he had had attacks of pressing pain in the midsternum, radiating into both shoulders and arms. These came on effort, especially walking, and would make him stop, whereupon the attack would let up. The attacks were relieved promptly by glyceryl trinitrate. Despite this he got along quite well until the fall of 1943, when attacks became frequent, even at rest, so that finally he used 10 to 15 glyceryl trinitrate pills daily.

The patient was very obese, weighing 100 Kg. There was no enlargement of the heart, the rhythm was regular and there were no murmurs. The lungs were clear and the abdomen was negative except for prominence due to obesity. No pitting edema was present. The urine was normal. The electrocardiograms showed slight rounding and inversion of T_1 , flat T_2 and sharply inverted T_4 .

He was put to bed in the hospital because of the frequent attacks of classic angina pectoris. Studies of the blood and other laboratory procedures were not remarkable. He was put on a diet of 1,000 calories, and promptly the attacks disappeared, so that he used only a few glyceryl trinitrate pills during his entire hospital stay, losing 10 Kg. in weight.

Because he had a stout abdomen he found it uncomfortable to lie perfectly flat. He also believed that attacks were more likely to come if he was recumbent. The result was that he

sat up in bed most of the time. We were quite encouraged at the quick disappearance of the anginal attacks, when on the twelfth hospital day he developed a slight fever of 101 F. and complained of feeling hot and cold and sweaty. Nothing abnormal could be found on physical examination until two days later, when he had definite pain in the gastrocnemius muscle on dorsiflexion of the left foot. He also had some mild pain in the left calf. The diagnosis of definite thrombophlebitis was made and because of the fear of pulmonary embolism a left femoral vein ligation was performed that very morning. From then on the leg did well, though a slight fever persisted for about ten days. He was ambulatory and much improved when he was discharged March 5, 1944.

This is a clear instance in which putting an obese patient to bed appeared to be directly responsible for the development of a deep phlebitis. Although the anginal state improved, the possibility of a fatal pulmonary embolism was averted only by the prompt ligation of the femoral vein. On retrospect one wonders whether it would not have been better to have him walk around. It certainly was unwise to allow this obese patient to sit in bed with the protuberant abdomen pressing on the veins of the groin a good part of the day.

COMMENT

Evidence has been presented to show that putting cardiac patients on a strict bed rest regimen entails certain hazards. When cardiac congestion is present, recumbency shifts fluid from the lower to the upper parts of the body. Edema fluid leaves the tissue spaces, enters the venous system, increases blood volume and increases venous pressure. These effects are probably temporary and transient in most cases and therefore do not appear to have any deleterious effects on the ultimate progress of the case. Not infrequently, however, this results in an aggravation rather than an improvement in pulmonary congestion, as the return flow to the right heart is enhanced, thereby increasing the output of blood from the right ventricle into the pulmonary vessels. When the left ventricle is still unable to meet this increase in work, as may happen in cases of hypertension, aortic valvular disease or coronary artery disease, dyspnea may grow worse. The same ill effects may be observed in some cases of mitral stenosis, in which the mechanical narrowing of the valve does not permit the added flow to reach the left ventricle. The situation is quite different if there is peripheral edema and engorged liver and there is no important threat of pulmonary congestion or dyspnea. In such cases recumbency will aid in diminishing right sided failure. These considerations do not vitiate the fundamental principle that rest is beneficial for heart failure. In fact, they actually substantiate this principle, because under certain circumstances recumbency is shown to increase rather than to decrease the work of the heart.

It has also become alarmingly apparent that many cardiac patients, after prolonged periods in bed, develop thrombosis of the veins of the legs with serious or fatal pulmonary emboli.⁸ This is explained partly on the immobility of the legs and partly as a result of pressure of the abdomen on the pelvic veins. The latter mechanism is very likely of considerable importance in obese individuals or in those suffering from orthopnea who have to sit up in bed. The sitting position assumed

8. Since this article was written, William Dock has published a paper emphasizing this same point, suggesting that pressure of the lower legs on the bed may play a role in causing thrombophlebitis in the gastrocnemius muscles (The Use and Abuse of Bed Rest, New York State J. Med. 44:724 [April] 1944).

by such patients must produce added pressure on these veins and thereby slows the circulation in the leg veins.

There are obvious therapeutic implications that follow from the foregoing observations. Some severely ill cardiac patients, especially those with nocturnal dyspnea, should not be kept flat in bed until active cardiac treatment has been well advanced in improving the circulation. During these early days they may sit in a chair and should be urged to exercise their legs or take short walks in their room several times daily. The bed in which they sleep should slant downward from head to foot. This can be accomplished by placing 9 inch wooden blocks under the head posts of the bed. In addition, the required number of pillows under the head should be used. Pillows alone do not meet the difficulty, as the purpose is to have the back and hips higher than the feet. Often it is best to have these patients sleep in beds raised in this fashion the rest of their lives. This may tend to prevent nocturnal dyspnea from returning. At times it is even wise to take a critically sick cardiac patient with severe pulmonary edema deliberately out of bed and place him in a chair with his feet hanging down. The purpose is to shift the fluid from the lungs to the legs. It would be better still if beds that embody this simple principle were generally available for cardiac patients at home and in hospitals.

The second precaution concerning bed care that is applicable to all patients, noncardiac as well as cardiac, who are to stay at rest for any considerable time is to have them exercise their legs frequently during the day. This is a practice that has already come into use to some extent. For the same reason, daily massage to the legs is desirable. The purpose is to prevent thrombosis of the veins of the legs and possible subsequent pulmonary emboli. In this regard, very obese individuals who are inclined to sit up in bed, or orthopedic patients who have to sit in the upright or semirecumbent position, need to be watched with particular care. The sitting position tends to produce pressure on the pelvic veins with slowing of the circulation in the veins of the legs, thus encouraging thrombus formation. It is believed that if attention is paid to the bodily position of the patient while instituting rest treatment our therapeutic results will be improved.

CONCLUSIONS

Rest in bed, which has been the backbone of our treatment of heart failure, needs reconsideration in the light of some possible harmful effects.

There is both clinical and laboratory evidence to show that recumbency may be very harmful for certain patients with heart failure. The heart may be made to work more rather than less, and pulmonary congestion may be made worse rather than better at certain stages of heart failure by placing the patient in bed. Making the bed slant downward by placing 9 inch blocks of wood under the head posts is a simple method of minimizing this undesirable effect. At times it is wise to treat patients with heart disease in a chair rather than in bed.

Cardiac as well as noncardiac patients who are confined to bed for any appreciable length of time should be instructed to exercise their legs frequently or to have massage of the legs to prevent venous thrombosis of the legs and pulmonary emboli.

270 Commonwealth Avenue.

THE ARMY AIR FORCES RHEUMATIC FEVER CONTROL PROGRAM

COLONEL W. PAUL HOLBROOK
MEDICAL CORPS, UNITED STATES ARMY

Rheumatic fever and its sequelae are of far greater significance in civilian life than is generally appreciated. Swift¹ indicates in his survey of New York State for 1938 that there were more than five times as many deaths from rheumatic heart disease as from whooping cough, measles, epidemic meningitis and anterior poliomyelitis combined. He also estimated that there were in excess of 460,000 individuals in the United States with rheumatic heart disease. Acute rheumatic fever has been considered as essentially a disease of childhood, but it has become a very serious problem among adults in the armed forces.

Under the supervision of the Air Surgeon, a program for the control of rheumatic fever and streptococcal infections has been established in the Army Air Forces. Credit for the success of the program belongs to the commanding general of the Army Air Forces, whose cooperation made it possible, and to the many medical and laboratory officers of the AAF hospitals, who have carried on these studies. The basic study was inaugurated in the spring of 1943, with forty of the larger AAF hospitals selected to cooperate in the investigation, representing approximately 25,000 beds and 800,000 troops. The posts chosen for the study were in areas of high incidence of rheumatic fever, areas of low incidence and intermediate areas. The geographic distribution of the areas studied is shown in figure 1. These hospitals, in addition to the usual laboratory facilities present at each, are served by ten strategically located and specially equipped laboratories for the grouping and typing of hemolytic streptococci.² Six hospitals located in the areas of lowest incidence were selected to receive patients with rheumatic fever for convalescence. The transfer to these hospitals is usually accomplished by air and can be carried out at a very early stage of the disease. For comparison, control groups are retained in the area in which the rheumatic fever was contracted.

At some air bases the incidence rates for the year 1943 were in excess of 25 per thousand troops involved (figs. 2 and 3). During the peak of the rheumatic fever season one large post experienced rates in excess of 100 per thousand annually. Other geographic areas showed a very low incidence. The total number of new cases for 1943 is large, but statistical data cannot be released at this time.

A consideration of the days lost from duty by this group, the long hospitalization, the large percentage of the group who will be permanently incapacitated, the inevitable compensation for disability and the future necessary medical care by veterans' facilities will indicate to some extent the magnitude of this problem.

The exact etiology and pathogenesis of rheumatic fever is still unknown. Whether it is a sequela disease

Read before the joint meeting of the Section on Practice of Medicine and the Section on Experimental Medicine and Therapeutics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

to a group A hemolytic streptococcus infection, the result of a congenital susceptibility, the result of climatic and meteorological factors, a combination of these or due to an agent as yet undiscovered remains for further studies to determine. Our experience and that of others indicates that in the majority of instances the development of the acute rheumatic fever syndrome is related to a preceding hemolytic streptococcus infection. At least it is certain that we have not seen an epidemic incidence of rheumatic fever without a preceding high incidence of hemolytic streptococcus infections. It therefore appears logical to attempt prophylaxis of rheumatic fever in those areas of high incidence by reducing or preventing the hemolytic streptococcus infections and the associated respiratory diseases.

This paper will deal only with one phase of the AAF Rheumatic Fever Control Program and will be limited to a report on the use of sulfadiazine prophylaxis. In March 1943 Painton³ at the Greensboro Army Air Base, while using sulfadiazine for the prophylaxis of meningococcic meningitis, obtained incidental evidence that scarlet fever could be controlled by this method.

The control of a scarlet fever epidemic among Navy personnel by the use of sulfonamides was similarly demonstrated by Watson and his associates⁴ at the same time. Others⁵ have reported favorable effects by the use of small doses of sulfonamides in preventing recurrences of rheumatic fever. Our studies of sulfonamide prophylaxis have been directed toward the determination of optimal dosage, the most effective method of mass

administration and an evaluation of the potential danger of the method. In our experience sulfadiazine, because of its low toxicity and availability, has been the drug of choice.

SULFADIAZINE PROPHYLAXIS

A number of carefully controlled studies were conducted, in which different methods of administration

Fig. 2.—Distribution of rheumatic fever in Army Air Forces installations for 1943. The open circles represent posts with rates less than one per thousand annually. The diameter of solid circles is proportional to rates at posts exceeding 1 per thousand annually.

were used and the amount of the drug given was varied. The treated groups and control groups were approximately the same size and represented as nearly as possible identical epidemiologic units. Most of the graphs shown are based on reduction of hospital admissions for respiratory disease and, at these posts, approximately 50 per cent of the admissions for respiratory disease showed clinical and laboratory evidence of significant hemolytic streptococcus infection.

Four grams of sulfadiazine given in a forty-eight hour period produces a definite but very brief reduction in hospital admissions for respiratory disease (figure 4,

Fig. 3.—A comparison of yearly incidence rates for rheumatic fever in two selected groups of AAF installations.

group B, approximately 5,000 troops). Six grams given over a period of three days promptly reduces the hospital admissions approximately 75 per cent for a period of about twelve days (fig. 4, group A, approximately 5,000 troops). One gram daily effects a continuous reduction in hospital admissions for respiratory disease and is somewhat more effective than the intermittent method if it is not properly timed (fig. 5, 5,000

B.: The Prophylactic Treatment of Rheumatic Fever by Sulfanilamide, *Bull. New York Acad. Med.* 18: 508-526 (Aug.) 1942.

troops in each group). The efficacy of 1 Gm. daily is clearly shown in relation to the control group in figure 6 (9,000 troops).

Striking reductions are obtained for total dispensary admissions by the same method (fig. 7, 9,000 troops). At two large bases almost identically satisfactory results

Fig. 4.—Sulfadiazine prophylaxis: A comparison of the effect of varying total dosage in control groups each containing 4,800 troops. Group A, solid line, 2 Gm. daily for three days. Group B, broken line, 2 Gm. daily for two days.

have been obtained in the reduction of the number of admissions to hospitals and dispensaries by the use of 0.5 Gm. daily.

When the effects of sulfadiazine prophylaxis are considered only in relation to streptococcal infections, the prophylactic value is even more dramatic, as might be expected (fig. 8, 4,800 troops in each group). This experience also indicates that intermittent and continuous dosage may be equally effective if properly timed. It further points out that, after a lapse of considerable time, prophylaxis when repeated on the same groups is fully as effective as the first time. Another post experience is shown in figure 9.

Fig. 5.—Sulfadiazine prophylaxis: A comparison of daily and intermittent dosage in two epidemiologically similar groups of 4,800 troops. Group A, broken line, 1 Gm. daily for twenty-two days; group B, solid line, 2 Gm. daily for two days.

With regard to the reduction in rheumatic fever, total figures are not yet available; but it appears from considerable data at hand that the reduction in rheumatic fever parallels the reduction in respiratory diseases and streptococcal infections.

DRUG REACTIONS

Painton³ at Greensboro Army Air Base in March 1943 gave each of 18,000 troops 4 Gm. of sulfadiazine in twenty-four hours without serious reactions.

Lee⁶ at Santa Ana Army Air Base gave each of 25,000 troops 2 Gm. in one dose and observed thirteen severe reactions. No deaths occurred. Seven had fever and all 13 had skin reactions. There were 15 additional cases of mild skin reactions. The very severe reactions occurred in individuals subsequently found to have a previous history of sulfonamide reactions that were not reported. Our special study of reactions has been limited to approximately 40,000 troops on which full reports are available. There were no deaths. Thirteen individuals lost some days of duty and 33 had mild manifestations not resulting in loss of time from duty. There were no renal complications and no evidence of neutrophilic leukopenia. The major disabilities were skin lesions occurring between the first and sixteenth days of administration of the drug. These disappeared when the drug was discontinued. In the only 2 indi-

Fig. 6.—Sulfadiazine prophylaxis: The effect of a daily dose of 1 Gm. on hospital admissions for upper respiratory disease, scarlet fever and pneumococcal pneumonia. The two control groups represent 9,000 men. Group A, solid line; group B, broken line.

viduals who developed high febrile reactions there was a history of previous sulfonamide reactions which had not been reported. One patient developed anemia, hemolytic in type, with prompt recovery following transfusions.

Of the 40,000 in this group, only 0.03 per cent lost time from duty and only 0.12 per cent had any type of reaction. Painton's experience with larger doses was similar. The reason for the increased incidence and severity of reactions observed by Lee at Santa Ana is not clear. Larger single doses have been used at a number of AAF installations for prophylactic purposes without a similar result. It is, of course, possible that by chance twice as many reactors were present in his group. However, the possibility of more sunlight at Santa Ana in consideration of the photosensitizing properties of sulfadiazine should be considered. At any rate it is quite obvious that the total hazard is very small and that, if known sulfonamide reactors are eliminated, doses of 0.5 to 1 Gm. daily can be given with almost complete lack of risk.

6. Lee, R. V. A.: Personal communication to the author.

COMMENT

Our army of seven million troops spent in excess of fourteen million days in the hospital last year because of common respiratory diseases. In addition to this time there were the inevitable number of complications and deaths as well as additional millions of man days lost from duty. If our experience with sulfadiazine prophylaxis holds true, it is a conservative estimate that 50 to 75 per cent of this tremendous loss could be avoided.

One question that will immediately present itself concerns the possibility of producing dangerous strains of sulfonamide resistant organisms. The answer cannot be given with complete certainty at this time. However, it is well known that patients who have had prophylaxis in the past respond equally well to sulfadiazine when an acute illness develops. Furthermore, as shown in figure 8, approximately ten thousand troops responded as well to a second period of prophylaxis as to the first. If sulfadiazine prophylaxis is to result in the production of dangerous sulfonamide resistant

Fig. 7.—Sulfadiazine prophylaxis. The effect of a daily dose of 1 Gm. on dispensary admissions for the same group shown in figure 6. Group A, solid line; group B, broken line.

strains, it would seem reasonable to expect that some evidence of this would already have appeared in our repeated experience on thousands of troops. To the best of our knowledge, such evidence has not yet appeared. Further bacteriologic studies are being directed toward this phase of the investigation.

The possibility of individuals becoming sensitized to the drug on a mass scale has been considered. Repeated periods of prophylaxis on the same groups have failed to demonstrate any developing sensitivity. Following the feeding of sulfonamides, late lesions developing in rats have been reported.⁷ Prophylactic doses used clinically are so minute when considering body weight that similar findings in human beings appear extremely unlikely. Further studies on animals, using comparable amounts of the drug based on body weights or blood levels over varying periods of time, should be undertaken. Three months has been the longest continuous period of prophylaxis used by us.

CONCLUSIONS

1. Acute rheumatic fever shows a striking geographic variation in its distribution, as indicated by the incidence rates per thousand troop population in the various geographic areas.
2. Acute rheumatic fever occurring in high incidence during this study in every instance has been preceded by a high incidence of hemolytic streptococcus infections.

Fig. 8.—Sulfadiazine prophylaxis: The effect of continuous and intermittent sulfadiazine administration on hospital admissions for streptococcal pharyngitis. The same group of 9,600 men was used in each of the two studies, which were done at an interval of one month.

3. A 50 to 75 per cent reduction in the incidence of respiratory diseases and streptococcal infections has been accomplished by the use of sulfadiazine prophylaxis under carefully controlled conditions and on a significantly large troop population. No serious drug reactions occurred.
4. From the partial data at hand, it appears that the reduction in rheumatic fever parallels that of respiratory and streptococcal diseases.

THE PREVENTION OF RESPIRATORY TRACT BACTERIAL INFECTIONS

BY SULFADIAZINE PROPHYLAXIS IN THE UNITED STATES NAVY

COMMANDER ALVIN F. COBURN, MC-V(S) U.S.N.R.
WASHINGTON, D. C.

The struggle between bacterial flora and the human host is a continuous one. Survival of the two has been determined by a balanced relationship. In time of war, living conditions of the host are such that this relationship is disturbed, and the balance is now already tipped in favor of respiratory pathogens. In the first year of World War II a significant development in the armed forces was the increasing morbidity rate from respiratory infections, and in the U. S. Navy the majority of the important respiratory diseases were caused by the hemolytic streptococcus. At U. S. naval training centers situated in Northern states these infections have handicapped recruit training. The experiences of one of these stations will illustrate the importance of streptococcal infections in the U. S. Navy.

Early in 1943 a training center with an average strength of 43,000 had an outbreak of measles. This was followed by many types of respiratory infections, including in one year 4,973 cases of scarlet fever, 1,375 cases of rheumatic fever, 1,383 cases of pneumonia, 131 cases of meningitis and at least 50,000 infections of the nasopharynx or tonsils. During the summer months the activity of the meningococcus and the pneumococcus subsided. However, the hemolytic streptococcus maintained its pathogenicity, and late in 1943 this bacterium manifested an increased virulence. It became highly communicable; it produced rather intense scarlet fever; it precipitated severe rheumatic attacks in susceptible subjects; it became invasive. The acquisition of invasiveness by this micro-organism was accompanied by the rapid development of lytic phenomena in the patient, e. g. vomica formation, pericarditis, empyema and other suppurative lesions. Furthermore, strains of this bacterium identified serologically as types 17, 1 and 19 maintained their pathogenicity when transplanted by carriers to other geographic environments and even initiated streptococcal outbreaks at naval activities situated in Southern states.

ECONOMIC LIABILITIES OF STREPTOCOCCIC INFECTIONS

Each man who is taken up on the sick list with a streptococcal infection becomes a liability to the Navy. Not only are his services lost but, in addition, the services of two well persons are required to care for him. The duration of his time on the sick list is determined by the streptococcus syndrome manifested. The average man-days loss for common diseases induced by the hemolytic streptococcus in 1942 and 1943 is presented in table 1. This table shows that the average time spent on the Sick List for scarlet fever was 21.9 days, for rheumatic fever 92.1, for pneumonia 26.4 and for tonsillitis 5.7 days.

From the Bureau of Medicine and Surgery, Navy Department. U. S. Navy Epidemiology Units numbers 67 and 89 supplied data used in this report.

Read before the joint meeting of the Section on Practice of Medicine and the Section on Experimental Medicine and Therapeutics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

Bacterial respiratory tract infections are costly not only in man-days loss but also in dollars expended. For example, the liability incurred for just four of these diseases at a single training station is conservatively estimated as shown in table 2.

A PROGRAM FOR THE CONTROL OF STREPTOCOCCIC INFECTIONS

The Navy's enormous loss to *Streptococcus haemolyticus* was only one of the compelling reasons for instituting a streptococcus control program. For military and civilian welfare it became essential to prevent the dissemination of the streptococcus among naval personnel, to prevent the induction of rheumatic fever with the development of incapacitating heart disease, to prevent the invasion of the streptococcus into deep tissues with the formation of suppurative lesions and to prevent the spreading of this highly virulent organism from one naval activity to another. To attain these objectives the U. S. Navy instituted a long term streptococcus control program in November 1943.

The first objective in this program was to check the dissemination of respiratory pathogens in the winter of 1944. For this purpose the use of prophylactic doses

of sulfadiazine seemed the method of choice. Other investigators had previously indicated the effectiveness of sulfonamide prophylaxis;¹ nevertheless, it seemed wise to control the administration of sulfadiazine with caution. To test the applicability of mass prophylaxis under controlled conditions and to determine a standard prophylactic dose of sulfadiazine, programs were designed for five large Northern training stations with high respiratory disease rates. Groups of trainees were then selected to receive sulfadiazine prophylaxis and comparable groups to serve as untreated controls. At each station these groups were placed under the surveillance of a Navy epidemiology unit consisting of two to five medical officers and four to ten pharmacist

Estimated cost in pensions for disabilities.....		\$10,000,000
Total cost for four streptococcus manifestations at one naval training station.....		\$15,000,000
Total man-days loss for four streptococcus manifestations at one naval training station.....		1,671,171

(c) To check the diagnoses of all men receiving sulfonamide compounds who were admitted to the sick list with respiratory infections.

(d) To obtain throat cultures on all such individuals and a sample (10 per cent) of individuals contracting respiratory infections in untreated control groups.

(e) To isolate the beta hemolytic streptococcus and ship these organisms in pure culture to the National Naval Medical Center, Bethesda, Md., for grouping, typing and testing of drug fastness.

On Dec. 1, 1943 this controlled program was initiated at five training stations. Data on the incidence of respiratory infections in the "treated" and control groups were collected for three months. With the accumulation of these data the effectiveness of mass prophylaxis was manifest. It was then decided to extend the program to three other naval activities experiencing a high incidence of streptococcal infections

and to discontinue the use of untreated controls in the five naval activities at which the sulfadiazine program was already in operation. Continuous mass prophylaxis was accordingly extended to about fifty camps of eight naval activities, and this program was continued throughout the spring months. The effectiveness of the overall program will be appraised in a forthcoming monograph.^{1a} The present paper is a preliminary report limited to observations on sulfadiazine prophylaxis instituted under three different conditions at three naval training camps.

THE EFFECT OF SULFADIAZINE PROPHYLAXIS INITIATED DURING A STREPTOCOCCIC OUTBREAK AT ACTIVITY A

Naval Activity A, situated in the city of Chicago, had experienced a high rate of infections occasioned by the great expansion of intensive training with a rapid turnover in personnel. Early in the winter its training program was seriously handicapped by a high incidence of streptococcal infections, which were subsequently identified as due to types 17, 3 and 30. During December 1943 more than 25 per cent of the station's complement were admitted to the sick list with respiratory infections, in all 27,966 man-days, or about 10 per cent of the available man power, were lost. The incidence of these infections continued to be high in January, and a large number of men developed rheumatic fever. By February 1944 the hospital admission rates² for respiratory diseases and sequelae had reached extraordinary heights: for catarrhal fever 988, for tonsillitis 426, for scarlet fever 171 and for rheumatic fever 70. The urgency of the situation and the expectancy of an increase in these rates during February and March

Chart 1.—A comparison of the monthly morbidity rates for respiratory tract infections at Activity A with those of other naval activities in the Chicago area.

were cogent reasons for placing all station personnel on sulfadiazine prophylaxis.

Results of Sulfadiazine Prophylaxis.—The institution of prophylaxis, 1 Gm. of sulfadiazine daily, on February 8 was followed by a rapid fall in the incidence of disease. For example, the scarlet fever rate² fell weekly to 70, to 45 and to 0 during the third week. The rheumatic fever rate rose during the first week of prophylaxis to 87 and then fell progressively by weeks to 45, 45, 19 and 6. The fall in incidence of respiratory diseases observed in February became even more pronounced in March and April 1944. That this was not to be expected from the experience of 1943 is shown in table 3. And it is seen in table 4 that this phenomenal change was not observed at other naval activities in Chicago during March and April 1944. A comparison of the monthly morbidity rates for respiratory infections at Activity A receiving sulfadiazine prophylaxis after February 8 and for five other naval activities in Chicago receiving no prophylaxis is shown in chart 1.

In summary, the institution of sulfadiazine prophylaxis 1 Gm. daily to all hands at Activity A on

2. Annual admission rates per thousand strength.

February 8 during a severe streptococcic outbreak was accompanied by a precipitous, contraseasonal decline in streptococcic infections and was followed by a striking drop in the incidence of rheumatic fever.

EFFECT OF SULFADIAZINE PROPHYLAXIS INSTITUTED IN HALF A CAMP AT THE ONSET OF A SCARLET FEVER OUTBREAK

Camp 1 of a naval training station had served as an untreated control group for the prophylactic program during the early winter months of 1943-1944. The

Chart 2.—The effectiveness of sulfadiazine prophylaxis as reflected by the incidence of scarlet fever in Camp 1 during the winter and spring months of 1944.

incidence of streptococcic infections among these 5,000 men had been moderate during December and January. About the middle of February the scarlet fever rate began to rise rapidly, and this was accompanied by a decided increase in the occurrence of other streptococcic respiratory diseases. Most of these infections, irrespective of the presence or absence of a scarlatinal rash, were caused by hemolytic streptococcus group A, type 19. On February 25 one half of the complement of this camp was placed on a prophylactic dose of 1 Gm. of sulfadiazine daily; the other half remained untreated. The effectiveness of sulfadiazine in preventing further

spread of this highly communicable strain of hemolytic streptococcus in recruits receiving prophylaxis is shown in chart 2.

EFFECTIVENESS OF SULFADIAZINE IN PREVENTING IMPLANTATIONS OF HEMOLYTIC STREPTOCOCCUS IN A RECRUIT CAMP

The foregoing observations indicated that 1 Gm. of sulfadiazine administered daily was effective in checking a streptococcic outbreak, either when well advanced (Activity A) or in its early stage (Camp 1). The following observations will serve to show that as little as 0.5 Gm. of sulfadiazine administered daily prevents the implantation of the hemolytic streptococcus in a

recruit group (Camp 2) with a complete turnover of personnel every four to six weeks.

Camp 2 was situated about 1 mile from Camp 1 on the same naval training station. In November 1943, when the incidence of streptococcic infections was low, this camp was divided into two groups for the purpose of this investigation. All even numbered companies were placed in group A, which received no chemo-

prophylaxis, and all odd numbered companies were placed in group B, which received 0.5 Gm. of sulfadiazine daily. On March 1 both groups were placed on a prophylactic regimen of sulfadiazine 1 Gm. daily. The incidence of respiratory symptoms and respiratory diseases of groups A and B is shown in chart 3. Data on the incidence of probable and frank hemolytic

Chart 3.—The effectiveness of continuous sulfadiazine prophylaxis in preventing respiratory tract infections in Camp 2.

streptococcus infections of the two groups are summarized in tables 5 and 6.

It is seen in chart 3 and tables 5 and 6 that the group receiving sulfadiazine prophylaxis had a low incidence of respiratory infections. This low incidence in group B was maintained for three months, and perhaps greater protection was afforded during March, when the prophylactic daily dose of sulfadiazine was increased from 0.5 to 1.0 Gm. The incidence of sick call visits for respiratory symptoms in the untreated group was twice

that in the treated group, and the incidence of respiratory diseases requiring bed care in the untreated group was about three times that in the treated group. In both the difference in incidence between untreated and treated groups is statistically significant. This difference is even more striking for streptococcal infections. The incidence of respiratory disease probably caused by the hemolytic streptococcus in the untreated group was eleven times the incidence of the treated group. Frank streptococcal infections in the untreated group had an incidence twenty-four times that of the treated group.

EVALUATION OF THE POTENTIAL LIABILITIES AND ASSETS OF SULFADIAZINE PROPHYLAXIS

When this program was initiated, there appeared to be three potential dangers inherent in sulfadiazine prophylaxis: (a) sensitization of patients to sulfonamide compounds, (b) induction of severe, irreversible drug reactions, (c) development of drug fastness by respiratory pathogens.

Sensitization of Patients.—Mild evanescent dermal drug sensitization phenomena occurred in all three groups receiving sulfadiazine. The incidence of symptoms ascribed to the drug varied between 0.2 and 0.7

Chart 4.—The ineffectiveness of two short courses of sulfadiazine in checking an outbreak of scarlet fever at a small naval activity.

per cent. Approximately half of these reactors when retested had no drug symptoms and were replaced on the prophylactic program. The large majority of all reactions occurred in the second and third weeks of prophylaxis following the total dosage of 7 to 20 Gm. of sulfadiazine. The reinstitution of prophylaxis in groups who had been without sulfadiazine for a period of one to four weeks did not increase the incidence of drug reactions. A few individuals who had manifested sensitivity to sulfonamide compounds and who subsequently contracted severe respiratory infections were treated with penicillin. The collected findings indicated that a small percentage of persons have an idiosyncrasy to sulfonamide compounds administered in therapeutic or prophylactic doses and that sulfadiazine prophylaxis per se does not sensitize.

Severe Irreversible Drug Reactions.—Dangerous untoward reactions occurred in 0.01 per cent of individuals receiving sulfadiazine prophylaxis. These were of two types and about equally divided between exfoliative dermatitis and granulocytopenia. With supportive treatment these disease processes appeared reversible. The administration of therapeutic doses of sulfonamide to one man with a sulfonamide rash and bronchitis was

followed by death. This was the only instance in which death occurred. The autopsy showed lymphadenopathy, which on microscopic examination proved to be leukemia.

Development of Drug Fastness by Respiratory Pathogens.—Fastness to sulfadiazine was apparently not initiated during the first four months of this prophylactic program. The evidence is:

1. There was no increase in the prevalence of any serologic type of hemolytic streptococcus in the groups on prophylaxis.
2. There was no increase in the proportion of hemolytic streptococci in the throat flora of individuals throughout the period of prophylaxis.
3. There was no increase in streptococcal morbidity throughout the period of prophylaxis.
4. There was no difficulty in obtaining a satisfactory therapeutic effect from sulfadiazine in individuals who contracted streptococcal infections while receiving prophylaxis.

In summary, the only liability incurred in this program was the development of a few severe drug reactions, 1 in 10,000 individuals receiving prophylaxis.

The gains from the program included prevention of disabilities, saving in man-days loss and a reduction in the costs for care of the sick and for pensions. The size of these gains was proportional to the incidence of bacterial infections of the respiratory tract. Among recruits with a high incidence of infections it was estimated that 343 man-days were saved per thousand weekly from bacterial infections. Most of these man-days were saved through the prevention of streptococcal infections. Since these infections are prone to cause debilitating sequelae, their prevention obviously created enormous benefits to Naval personnel and to the United States government in a state of war.

COMMENT

A number of observers have pointed out the effectiveness of a short course of sulfadiazine prophylaxis in checking outbreaks of meningococcal infections.³ This measure not only breaks the epidemic process but also eliminates the meningococcus from the throat flora of carriers. Because of this misconception has arisen in the handling of streptococcal outbreaks. Sulfadiazine administered for a few days, either in prophylactic or in therapeutic doses, does not check a streptococcal outbreak and has little or no effect on the throat flora of individuals in the carrier state. This fact was demonstrated by a small naval activity experiencing an outbreak of scarlet fever. Sulfadiazine was given for three days in January with apparently good results; however, the outbreak recurred in February when another three day period of prophylaxis was administered with little effect. All personnel were subsequently placed on a continuous prophylactic program of sulfadiazine 1 Gm. daily, early in March. The streptococcal outbreak then subsided and only 2 new cases of scarlet fever occurred in the following ten weeks. The ineffectiveness of short courses of sulfadiazine at this activity is shown in chart 4. This experience illustrated that a three day course of prophylaxis, which will effectively check a meningococcal outbreak, is not adequate for preventing streptococcal infections. The presence of sulfadiazine on the surface of mucous membranes prevents

3. Cheever, F. S.; Breese, B. B., and Upham, H. C. The Treatment of Meningococcus Carriers with Sulfadiazine, *Ann. Int. Med.* **19**: 602-608 (Oct.) 1943. Thomas, H. M., Jr. Meningococcal Meningitis and Septicemia. Report of Outbreak in Fourth Service Command During Winter and Spring of 1942-1943, *J. A. M. A.* **123**: 264-272 (Oct. 2) 1943. Kuhn, D. M.; Nelson, C. T.; Feldman, H. A., and Kuhn, L. R. The Prophylactic Value of Sulfadiazine in the Control of Meningococcal Meningitis, *ibid.* **123**: 335-339 (Oct. 9) 1943.

implantation of hemolytic streptococci but does not modify the streptococcus flora already implanted.

The exact concentration of sulfadiazine in the nasopharyngeal secretions required to prevent implantation of bacterial respiratory pathogens is still unknown. In the course of the present studies it was found that individuals receiving a daily dose of 1 Gm. of sulfadiazine had blood values ranging between 2.6 and 1.7 with a median of 2.2 mg. per hundred cubic centimeters and that with a daily dose of 0.5 Gm. the blood values ranged between 1.8 and 0.8 with a median of 1.4 mg. per hundred cubic centimeters. The findings of others⁴ have shown that the concentration of sulfadiazine in the secretions of the upper respiratory tract is about 60 per cent of blood levels. The observations made in Camp 2, therefore, indicate that these secretions containing less than 1 mg. of sulfadiazine per hundred cubic centimeters were adequate to prevent the implantation of most bacterial respiratory tract pathogens.

SUMMARY

1. The United States Navy is engaged in a long term program for the control of streptococcal infections and their disabling sequelae.

2. One component of this program involves mass prophylaxis with sulfadiazine.

3. Prophylactic doses of this drug were given continuously to about 250,000 naval trainees between December 1943 and April 1944.

4. This preliminary report deals with observations on only 30,000 men at three camps.

5. These observations indicate that the continuous ingestion of 1 Gm. of sulfadiazine daily is adequate (a) to check a well advanced streptococcal epidemic, (b) to check a streptococcal outbreak at its onset and (c) to protect 85 per cent of susceptible recruits from implantation with bacterial respiratory pathogens.

6. These observations also suggest that a continuous daily dose of 0.5 Gm. of sulfadiazine (affording a mean level of 1.4 mg. per hundred cubic centimeters in the blood and perhaps 0.8 mg. per hundred cubic centimeters in secretions of the respiratory tract) is almost 85 per cent effective in preventing implantation by *Streptococcus haemolyticus*.

7. The only untoward effect of mass sulfadiazine prophylaxis is the occurrence of evanescent rashes in 0.5 per cent and dangerous constitutional disturbances in 0.01 per cent.

8. Mass sulfadiazine prophylaxis is effective (a) in checking bacterial infections of the respiratory tract, (b) in preventing the development of disabling sequelae caused by these bacteria and (c) in aiding the economy of a nation at war.

ABSTRACT OF DISCUSSION

ON PAPERS OF COLONEL HOLBROOK AND
COMMANDER COBURN

DR. T. DUCKETT JONES, Boston: I have no doubt that the general contentions of both speakers are absolutely true. There can be little doubt that sulfadiazine in dosages as indicated and administered as indicated will definitely affect the illness rates, particularly those caused by hemolytic streptococci. I do not think the question of sensitivity to these drugs is yet answered. Sensitivity may not develop until many months after the cessation of the preventive administrations. That is a serious problem, and I wonder if either speaker had any means whereby he might evaluate the question of development

of sensitivity in any of the men receiving the drug. Commander Coburn showed some stations that were control stations. In my experience there have been great differences in illnesses, so that this type of control must be difficult. Neither presentation showed bacteriologic charts, but apparently the charts included bacteriologic infections. The only data at present with regard to rheumatic fever are those of Colonel Holbrook, and I saw no significant difference in the group as he presented it. In conclusion I should like to suggest that perhaps we may control the major features of streptococcal illness by giving the drug to small groups of men who constitute a single epidemiologic unit and base conclusions on the actual illness experiences in these groups. We know that at least 50 per cent of the men will not need preventive measures. It is possible that the drug can be used intelligently to prevent the maximum amount of disease by giving the drug to the minimum number of men.

CAPTAIN RICHARD G. HODGES, M. C., A. U. S.: In evaluating an epidemiologic experiment on respiratory disease it is necessary to exercise considerable caution because there are a number of factors which can cause considerable variation in the respiratory disease rates. In the military population the seasoning of the troops is extremely important. The living conditions of the troops, particularly as pertain to ventilation and dust, the duties of the troops and finally the inflow of new material into the population may also cause profound changes. It is possible that the mass of Commander Coburn's material makes careful control of these factors somewhat unnecessary. However, to substantiate his contentions I should like to mention my experience at an Army Air Force technical school where a considerable degree of control was possible. The school was almost ideally set up for a controlled experiment, being divided into two teaching shifts of approximately 5,000 men each. The duties, the living conditions and even the recreations of the two groups were identical. They were on different time schedules, and thus mixing between the two was at a minimum. Percentage distributions according to length of stay on the field, according to the length of service and according to age were approximately the same for the two. The inflow of new troops into these two groups was approximately equal. Finally, for the preceding fifteen months component squadrons of the school were found to have behaved similarly toward respiratory disease and to an approximately similar degree. During January both groups showed a progressive rise in rate. On the 2d, 3d and 4th of February the members of one teaching shift received 2 Gm. of sulfadiazine per day. Their rate dropped sharply, while the control group's continued to rise. The drop lasted ten days. Then the other group was placed on 2 Gm. a day for two days and showed a corresponding but somewhat less prolonged response. Finally one group was placed on a continuous dosage of 1 Gm. a day and the other group was placed on 2 Gm. a day for two days, and then that was repeated one week later. Both dropped sharply. The response was greatest in streptococcal infections. The streptococcal disease rate was lowered almost to zero by each administration. Thus I believe that the effectiveness of the treatment with sulfadiazine is established.

COMMANDER ALVIN F. COBURN (MC), U.S.N.R.: There are two points that I should like to mention before the conclusion of this discussion. One is that conditions in naval training camps lend themselves well to controlled studies. Alternate companies can either be given prophylaxis or serve as untreated groups. Accurate data can be obtained. Except for the one program which, as I stated, was instituted during an epidemic at a naval activity here in Chicago, all of the navy studies were controlled. Companies selected in random fashion mingled and slept in the same barracks, used common mess halls and exercised together in common drill halls. These studies in the effectiveness of chemoprophylaxis were made under ideal conditions. The second point, which was mentioned only briefly, is that sulfadiazine prophylaxis was effective in preventing rheumatic fever. The incidence of rheumatic fever among men receiving chemoprophylaxis was 15 per cent of the incidence in control groups. Approximately 85 per cent of the expected rheumatic fever cases appeared to be eliminated by sulfadiazine.

⁴ Norris, C. M.: Sulfonamides in Bronchial Secretion: The Effect of Sulfonamides in Bronchiectasis, J. A. M. A. 123: 667-670 (Nov. 13) 1943.

DR. ROY W. SCOTT, Cleveland: Are there any advantages of sulfadiazine over sulfathiazole?

COLONEL W. PAUL HOLBROOK, M. C., A. U. S.: Dr. Jones asked about what is being done to determine the question of sensitivity. The possibility of individuals becoming sensitized to the drug has been considered. As yet, evidence for an increasing sensitivity in individuals who are on the prophylactic program is not available. Repeated periods of prophylaxis on the same groups have shown in each instance a decreased number of reactors for the second or third prophylactic period rather than an increase. Once the known positive reactors are eliminated, no further difficulty is encountered during subsequent periods of prophylaxis. We also now have a rather large number of troops who have had prophylactic sulfadiazine and who have subsequently developed an acute illness requiring the administration of sulfadiazine therapeutically. These patients have responded as well as those not having had a prophylactic period. These experiences do not appear compatible with an increasing sensitivity. A long range study is planned by means of recording each individual's prophylactic record on his immunization register, so that in six months or a year a rather large accumulation of information should be available on this subject. I have not used sulfathiazole, largely because of the general reports in the literature as to its increased toxicity, but I have no experience in its use for this type of prophylaxis.

THE TREATMENT OF TONSILLITIS WITH SMALL DOSES OF SULFONAMIDES

CAPTAIN EDWARD D. FREIS

MEDICAL CORPS, ARMY OF THE UNITED STATES

From both military and economic aspects, any relatively nontoxic therapy which will shorten the course of a prevalent disease, if even for a few days, is worthy of application. Since it is generally acknowledged that tonsillitis is responsible for a significant number of the total man hours lost to industry and the armed forces, the advisability of treating acute follicular tonsillitis with sulfonamides has been the subject of a variety of studies. From the medical point of view, chemotherapy would be desirable because of the possibility that such complications as peritonsillar abscess and such sequelae of tonsillitis as nephritis and rheumatic fever might be prevented or at least minimized.

The advisability of using large doses of sulfonamides (2 Gm. or more per day) in the treatment of tonsillitis remains controversial. Some believe that, since this disease is relatively benign and self limited, chemotherapy is unnecessary and even dangerous.¹ This view is supported by the number of serious toxic reactions that have resulted from the indiscriminate use of the sulfonamides. Others believe with Gettelman and Kaiz² that early treatment with sulfonamides (2 Gm. per day) appreciably shortens the course of the disease.

From the AAF Rheumatic Fever and Streptococcal Disease Control Program.

Lieut. Col Robert King, M. C., and Dr. Chester S. Keefer cooperated with suggestions and criticisms.

2. Gettelman, L., and Kaiz, S. P.: The Treatment of Severe Tonsillitis in a Naval Dispensary, *U. S. Nav. M. Bull.* 42: 199 (Feb.) 1944.

A middle of the road point of view is taken by Janeway,³ who prescribes chemotherapy only for those patients whose temperature exceeds 102 F.

In addition to systemic therapy, the local treatment with sulfonamide sprays has become popular. Many investigators have reported effective therapeutic results and an absence of drug reactions following the use of local sprays in the treatment of various upper respiratory infections.⁴

In order to establish the relative efficacy of the local and systemic administration of sulfonamides in the treatment of acute follicular tonsillitis we considered it necessary to study this question under controlled conditions using hospitalized patients.

METHOD

During the winters of 1943 and 1944 a series of 405 young men of military age who had definite clinical evidence of acute follicular tonsillitis were hospitalized to a separate ward devoted to their care. During the first year of the study the patients were divided into two groups, alternate patients being treated by one of two methods. One group (1) of 100 patients were given only hot saline irrigations every four hours and received no chemotherapy. The other group (2) of 100 patients were treated with hot saline irrigations every four hours and in addition received sulfanilamide spray to the tonsils and pharynx every two hours except while asleep. Powdered sulfanilamide was sprayed into the throat until an even white coating of the mucous membranes was produced, the patient being then instructed to swallow, following which the throat was again sprayed.⁵ The amount of sulfanilamide used per dose varied from 75 to 100 mg. and, as eight applications were administered daily, the total daily dosage varied from 500 to 800 mg. With this dosage blood sulfanilamide levels were never found to be above 1 mg. per hundred cubic centimeters and usually were too low to be read by standard methods.

During the second year group 3, consisting of 115 patients, received saline irrigations every four hours and, in addition, 125 mg. of sulfadiazine by mouth four times a day (500 mg. daily). The sulfadiazine was in tablet form and was swallowed immediately. Another group (4) of 90 cases was treated in the same way as group 2 except that "microform crystals" of sulfadiazine⁶ were substituted for sulfanilamide powder.

On admission a throat culture and white blood count were obtained. Patients who showed peritonsillar abscess, fusospirochetal ulcers of the tonsil, scarlet fever, acute glomerulonephritis or rheumatic fever on admission were not included in this study. Similarly excluded were patients who had the common cold with nasopharyngitis and tonsillar swelling without pronounced redness or follicles.

As indicated in the table, the four groups were essentially similar in regard to admission temperature, infecting organism and average admission leukocyte counts.

6. Smith, Kline and French laboratories supplied the sulfadiazine microform crystals.

RESULTS

The groups which received sulfonamides (2, 3 and 4) either locally or systemically showed a return to normal temperature and "clinical recovery" in an appreciably shorter period of time than the control group (1) treated with irrigations alone (as shown in the table). Statistical examination of our data reveals that a reliable difference exists between group 1 and the other (sulfonamide treated) groups, since the reliability of the differences of the control group as compared with each of the sulfonamide treated groups is greater than three.

The criteria for "clinical recovery" were complete subjective relief of symptoms and complete disappearance of erythema, edema and follicles. Many of the patients, particularly in the sulfonamide treated groups, were subjectively well before the signs of inflammation had completely subsided. Hence it is probable that in other hands this period of "to clinical recovery" might be shorter or longer. Obviously this interim has not the same objectivity as "return to normal temperature" and therefore is not equally significant.

4 and group 2 can be attributed to the well known fact that sulfadiazine is more effective in infections caused by the hemolytic streptococcus than is sulfanilamide.

The fact that the patients in group 3, who received 0.5 Gm. of sulfadiazine daily in tablet form, showed a rate of recovery comparable to the groups receiving local spray raises the question of the advisability of using topical therapy in the treatment of tonsillitis. As tablets are more easily administered than local spray, there is no clinical reason for the use of the latter in the treatment of this condition.

The saving of even one day in hospitalization has much economic and military importance, since, when the incidence of tonsillitis is considered, this saving can be translated into terms of thousands of man-days salvaged. In view of the fact that the patients receiving sulfonamides experienced subjective relief even though some residual signs of subsiding inflammation remained, it is possible that such patients can be discharged to military duty or to industry as soon as the temperature becomes normal, with the stipulation that they con-

Summary of Data

Groups	No. of Cases	Temperature on Admission	White Blood Cells on Admission, Thousands	Positive Hemolytic Streptococcus	Days to Normal Temperature				Days to Clinical Recovery				Complicating Peritonsillar Abscess
					Mean	S. D.	S. E. M.	Reliability of Difference	Mean	S. D.	S. E. M.	Reliability of Difference	
1	100	101.6 (98.8-104.2)	13.7 (5-24)	83	3.3	1.63	0.163	...	4.7	1.95	0.195	...	6
2	100	101.7 (98.6-104.6)	13.6 (5-23)	85	2.3	1.07	0.107	5.0	3.5	1.44	0.144	5.0	1
3	115	101.7 (99.2-104.8)	12.5 (5-22)	86	1.6	0.58	0.058	9.1	3.6	1.24	0.116	4.9	1
4	90	101.4 (98.6-104.5)	12.6 (5-26)	78	1.4	0.73	0.077	10.2	3.0	1.15	0.121	7.4	0

$$S. D. (\text{standard deviation}) = \sqrt{\frac{\sum d^2}{n}}$$

$$S. E. M. (\text{standard error of mean}) = S. D. / \sqrt{n}$$

$$\text{Reliability of difference} = \frac{\text{Difference between means}}{\sqrt{(S. E. M._1)^2 + (S. E. M._2)^2}} \quad (\text{all comparisons made between group 1 and the other groups}).$$

The control group (1) showed an incidence of 6 cases of peritonsillar abscess, which developed as a complication during the period of hospitalization. In both the sulfanilamide spray treated group (2) and in the group receiving sulfadiazine tablets (3) one complicating peritonsillar abscess developed, while none occurred in the group receiving microform crystals of sulfadiazine as a local spray.

The data reveal that the temperature returned to normal more rapidly in the sulfadiazine-treated groups (3 and 4) than in the sulfanilamide spray treated group (2). The group receiving sulfadiazine microform crystals locally (4) seemed to be the most benefited. However, the differences between the various sulfonamide treated groups are not of sufficient significance to merit separate discussion.

None of the patients who received sulfonamides developed either toxic reactions or evidences of sensitization.

COMMENT

Our data demonstrate that small, nontoxic doses of sulfonamides will appreciably reduce the period of illness associated with tonsillitis, irrespective of the route of administration of the drug. That the difference between the sulfonamide treated groups and the control group is real is indicated by statistical examination of the data. The small difference between groups 3 and

4 and group 2 can be attributed to the well known fact that sulfadiazine is more effective in infections caused by the hemolytic streptococcus than is sulfanilamide.

It is possible that the use of more than 500 mg. of sulfadiazine daily would have further hastened recovery. However, when dealing with a potentially harmful drug, a balance must be struck between effective and toxic dosage. The complete absence of sulfonamide reactions in the treated groups favors the use of small dosage in the treatment of tonsillitis. This does not imply that these small doses of sulfonamides necessarily are effective in other infections.

CONCLUSIONS

1. The administration of small doses of sulfonamides appreciably shortens the course of acute follicular tonsillitis and minimizes the complication of peritonsillar abscess.

2. Small doses (500 mg. per day) of sulfadiazine administered by mouth in tablet form are as effective as the local application of sulfonamides to the tonsillar area in the form of a powder spray. The ease of administration makes the systemic route the ideal therapeutic procedure.

3. There were no toxic or sensitization reactions observed in any of the 305 patients receiving sulfonamides in the doses given.

Clinical Notes, Suggestions and New Instruments

HEMOGLOBIN ESTIMATION BY THE REVOLUTIONARY COLORIMETRIC METHOD OF KENNEDY

WITH FURTHER REPORT ON A SIMPLE INSTRUMENT FOR FACILITATING THE UTILIZATION OF THE PRINCIPLE

DON H. DUFFIE, M.D., CENTRAL LAKE, MICH.

In 1926 Robert P. Kennedy¹ published a method of colorimetry, for hemoglobin especially, that was so new, so valuable, that it is indeed regrettable that the very scholarliness of his paper seems to have concealed his discovery from most of us.

With the exception of spectrophotometry, practically all previous colorimetry had comprised sundry expedients for the matching of colors. In Kennedy's hemoglobin method, by means of a light filter transmitting such a narrow band of wavelengths in the green as to be virtually monochromatic, he simply eliminated color from both standard and unknown, then matched light intensities instead—a totally different concept.² He could do this—and this is the whole point—because, as seen through his filter, red and gray both appear green. Not merely green, but when illuminated to equal brightness both appear of the identical hue of green.

I have stated before³ the basic principle as applied to hemoglobin, that green light is absorbed by a red solution. The more red substance present, the less green light will get through, so that by suitably measuring how much does get through the amount of the red substance (oxyhemoglobin) may be computed.

As Kennedy points out, color filters had been employed in colorimetry as far back as Leonardo da Vinci in the sixteenth century, but to the best of my knowledge always either as a means of facilitating color matching or else in the absurd quest of finding an exact additive color complement for each and any color, so that the combination might then be compared in intensity with white light.

The bold idea of cutting loose from color entirely, of doing with our own eyes exactly what the photoelectric colorimeter does—quantitative measurement of colored light—that, so it is believed, was new with Kennedy. In spite of his superb work, however, said photoelectrics have right to date enjoyed virtual if quite unwarranted monopoly of the principle. Kennedy's hemoglobin method does sound cumbersome: indeed it was never propounded as a clinical method, though it may readily be adapted as such very satisfactorily.⁴

Unaware of Kennedy's work until it was brought to my attention by another⁵ who found himself inadvertently trespassing on Kennedy's domain, I, a country doctor and reformed color process photograver, had arrived at the same idea empirically, thanks to years of familiarity with light filters in

the trade. Kennedy used an ordinary colorimeter, a number 74 filter, one cup replaced by a fixed gray standard, the solution depth in the other cup varied as needed to secure a luminosity match with the gray standard. I applied the principle in reverse, keeping the solution layer constant and securing a match by varying the gray, in the form of an optical wedge. This application lends itself to a less elaborate instrument, a less expensive one, and one considerably quicker to use. The scale, for direct reading through the eyepiece, is superimposed on the margin of the wedge. This instrument that I have devised is a plungerless, one cup colorimeter (more correctly, photometer) using a micrometer measured Kahn vial for solution cup and having my own green filter incorporated in the eyepiece. One time saving feature of this construction when used for hemoglobin is that, while a precise 20 cu. mm. of blood must be used, the volume of diluent need not be measured at all. This is because light reaching the eye vertically through the solution will have encountered a constant quantity of blood per unit area, be the depth little or much. (It is ever a disappointment when any one fails to argue this point!) The test can readily be done in less than one minute.

CALIBRATION

Aware of having neither ability nor facilities for the quest of the absolute in hemoglobin values, I am content, in calibrating my instrument, to strike a compromise among the weird chaos of calibration levels of instruments already on the market, in which discrepancies of more than 3 grams are found! Since in this type of instrument there are economic and other objections to continuing the wedge down to zero, mine has been arbitrarily restricted to the range between 5 and 20 Gm. of hemoglobin. For zero set, readings are made from a sheet of permanent gray standard, and, in event of the gray not giving a

match at the supposed value, the lamp of the instrument is adjusted in position until it does. One advantage of such an arrangement is that it gives free rein to individual convictions in the matter of calibration levels, which may be "remodeled to suit tenant" in a moment. The critic need but set the instrument scale to read whatever his own oracle decrees the blood in question should read and then adjust the lamp position, if need be, until it does. The gray standard is then read at the new setting and labeled accordingly. Stability is thus assured until another Pharaoh arises! This permanent gray standard may be either an Eastman neutral density filter in glass, density 1.0, two layers of fine monel or other screen in glass as suggested by Sunderman,⁵ or my present preference, a small square of engraver's halftone screen.

Fig. 1.—Simple photometer employing Kennedy's principle. Fields are matched by manipulation of an optical wedge moving in the sleeve at right of ocular. Scale is read through the eyepiece.

The instrument is not in commercial production "for the duration." A few of the instruments are being built in the author's hobby shop.

1. Kennedy, R. P.: The Use of Light Filters in Colorimetry, with a Method for the Estimation of Hemoglobin, *Am. J. Physiol.* 78: 56 (Sept.) 1926.

2. Should any suspect this to be distinction without difference, let him ponder the unequal scale divisions, so much farther apart in the lower concentrations, of any hemoglobin instrument employing the wedge principle on a color matching basis. Contrast this with the scale divisions in equal parts throughout, where the wedge is used on the Kennedy principle, as in my own photometer.

3. Duffie, D. H.: The Elimination of Color from Visual Hemoglobinometry, *J. A. M. A.* 119: 493 (June 6) 1942.

4. But meager outline may be given here. A colorimeter cup not more than 12 mm. in diameter is preferable. A piece of Eastman neutral density filter of density 0.5 mounted in glass replaces one colorimeter cup. If brilliant illumination is available, Wratten number 74 filter is laid over the eyepiece, if not, one layer of number 15 and two layers of number 60 film filter. (For some eyes one layer of 60 is enough to exclude all red.) In the remaining colorimeter cup 0.02 cc. of blood (Sahlb pipet) in 5 cc. of 0.4 per cent ammonium hydroxide solution is placed and the fields are matched. My own experience with such an instrument is too scanty for dogmatism, but, by trial with known blood dilutions a factor may be worked out which, divided by plunger height (decimal point appropriately inserted) will give the hemoglobin in grams per hundred cubic centimeters. The factor 1.7 is believed to be not greatly in error. Once a table or curve for direct reading of results is prepared, the method is rapid.

5. Sunderman, F. W.: Personal communication to the author.

ACCURACY

Karr and Clark,⁶ in hundreds of determinations by several of the commoner hemoglobin methods, after applying all corrections found fewer than one half of the readings to be within

6. Karr, W. G., and Clark, J. H.: Comparison of Various Hemoglobin Methods as Performed in Hospital and Physicians' Laboratories *Am. J. Clin. Path. (Tech. Supp.)* 5: 127 (Sept.) 1941.

0.5 Gm. (3 per cent) of the mean. In a test later reported by one of them⁷ on my instrument, in which two of the three observers had had no practice, 95 per cent of the sixty readings were within 0.25 Gm. of the mean (1.5 per cent). This is indeed a precision often unattained by the photoelectrics.

The secret of this higher precision is believed to lie in the filter employed. The retina evidently has heightened sensitivity to minute differences in intensity for wavelengths transmitted by this filter when shielded from the "glare" of waves excluded by the filter's absorption

BLOOD CHEMISTRY

Not knowing (fortunately) that maximum filter transmission theoretically should be restricted to a wavelength range coinciding with the maximum absorption of the solution to be tested, so that a different colored filter would be required for nearly every color of solution measured, I went ahead, using my same green filter for all the blood chemistry filtrates I could find. Before learning from wiser heads that this could not be done, I had done it. Entirely satisfactory readings were obtained, which plotted as almost straight lines, from

Fig 2—Transmission curves of Kennedy's filter (K), Duffie (D), shown against the absorption curve of oxyhemoglobin.

blood sugar, creatinine, urea, phosphorus, tyrosine, total protein, Haslam's⁸ unpublished serum protein method, nonprotein nitrogen and all modifications tried of the Bratton-Marshall sulfa-concentration method. The case with creatinine is interesting. The filtrate itself gives perfectly sharp readings, whereas the bichromate standards, indistinguishable to the eye from the respective filtrates, give no readings whatever with this filter. It was to me surprising that the greens of the blood cholesterol test can also be closely read through the green filter, though they plot a sharply inflected curve. While it is true that with one or two of these solutions this filter does not give an absolute hue match, even so, the only blood chemistry test I have found on which it will not give satisfactory readings is the yellow of the sulfonamide concentration test with Ehrlich's reagent. The saving of the technician's time is obvious if standard solutions need be run but once for calibration then occasionally as check on reagents.

7. Karr, W. G.: Personal communication to the author in October 1942.

8. Haslam, T. P.: Personal communication to the author. (According to Haslam's equation, if for blood sugar precisely 3 cc. of the filtrate is used in my instrument, a cipher added to the gram scale reading gives the sugar in milligrams per hundred cubic centimeters.)

CALIBRATION FOR OTHER TESTS

Once a set of four or five standard solutions have been processed, in strengths covering the usual clinical range of the test, calibration is almost quicker done than fully described. Briefly, readings are obtained in the instrument from suitable and precisely equal volumes of these standard solutions, plotted on graph paper against the known concentrations of these solutions, and a standard curve drawn. Values of identical volumes of unknown solutions may then be instantly evaluated in terms of concentration, from the curve. Having done which, one may be reasonably sure of his results and need take no man's word for anything.

SULFONAMIDE CONCENTRATION TESTS

Readings of sulfonamide drug concentration tests by any method using Marshall's reagent may be done so accurately on this instrument, with the same filter and from such small amounts of blood, that truly micro volumes may be used, 0.02 cc. of blood instead of 0.2-0.3 cc., as in several micro methods.

TWO CASES OF CLOSTRIDIUM WELCHII INFECTION TREATED WITH PENICILLIN

MAXWELL KEPL, M.D., ALTON OCHSNER, M.D., AND
J. LEONARD DIXON, M.D., NEW ORLEANS

We believe that the development of gas gangrene in a traumatic wound depends on four factors: (1) contamination of the wound with soil or foreign bodies containing clostridia, (2) inadequate blood supply to the affected part, (3) inadequate débridement and (4) conditions in the wound for anaerobic growth. A combination of these four factors in a given patient will almost invariably give rise to clinical "gas gangrene."

Once clinical "gas gangrene" has fully developed, the only known treatment is radical surgery, laying the affected parts wide open and many times, of necessity, doing a high guillotine amputation in order to save the patient's life.

Any chemical or biotic substance which will inhibit the growth of clostridia in traumatic wounds would be of inestimable value in saving limbs and lives.

The discovery by Fleming¹ of the action of penicillin and its use by McIntosh and Selbie² in experimental *Clostridium welchii* infections held promise that this drug would be of value in such infections. As animal experiments are inconclusive in regard to human therapy, it remains for the clinician to put penicillin to the final test in regard to its efficacy in the treatment of gas gangrene. The recent report of Keefer, Blake, Marshall, Lockwood and Wood³ indicates that more clinical observation on the action of penicillin in "gas gangrene" infection is needed in human cases before definite conclusions can be drawn. Lyons⁴ also makes a similar plea.

McKnight, Loewenberg and Wright⁵ have reported their experience in a case of "gas gangrene." They could not control the "gas gangrene" infection with wide incisions, sulfathiazole systemically, large doses of gas antitoxin and high voltage x-ray therapy. A high arm amputation was resorted to, but

Leah Seidman Shaffer, ScD, made the bacteriologic studies from the Department of Surgery, School of Medicine, Tulane University.

Dr. Kepl is fellow in orthopedic surgery, Division of Medical Sciences, National Research Council.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Tulane University of Louisiana.

gas bubbles persisted in the axillary wound. Intravenous sodium penicillin in isotonic solution of sodium chloride was given continuously on the second postoperative day until the edematous condition of the patient made it necessary to stop therapy. In addition, the patient received 40,000 units directly intramuscularly into the stump. During the next week the temperature gradually dropped, and the wound cleaned up. No positive bacteriologic identification of the causative organism was done, owing to inadequate laboratory facilities. It was agreed by four experienced clinicians, however, that the case was one of clinical "gas gangrene."

Recently we have had occasion to study two cases of *Clostridium welchi* infection, both of which were treated with penicillin. In one, following a shotgun injury to the lateral aspect of the thigh, there was no evidence of clinical "gas gangrene," but a persistent *Cl. welchi* cellulitis associated with *Staphylococcus aurantiaeus*, coagulase positive, and a gram negative anaerobic bacillus, unidentified as yet. Calcium penicillin was applied directly to the wound in a dilution of 5 cc. of isotonic solution of sodium chloride containing 20,000 units. Local administration of this dosage was continued for six days. Cultures were taken before, during and after penicillin therapy. Under local penicillin therapy the number of gram negative organisms and *Staphylococcus aurantiaeus* appeared reduced in direct smear preparation with an increase in the number of

Fig 1—Arm and forearm, edematous, "wet" and ischemic before penicillin and surgery. Note the multiple bullae.

cocci phagocytized. The clostridia found lacked a good capsule but persisted undiminished in the wound throughout penicillin therapy. A milk tube inoculated with a swab consistently showed "stormy" fermentation. The wound healed slowly by granulation over a period of seven weeks, and at no time was the patient's general condition impaired by the *Cl. welchi* cellulitis.

The second case was that of a man whose arm was lacerated by broken glass which severed the biceps, the brachialis, the radiobrachialis muscles, the brachial artery, the radial and median nerves and the median basilic vein. Bleeding was severe, and a tight tourniquet was put on before he entered the hospital. Complete débridement and closure were done early, followed by repeated stellate blocks and packing of the injured extremity in ice. The temperature, 100 F. on admission, went to 102 F. the next day. The fingertips were inspected at that time and found warm and pink. The patient began to complain of severe pain in the arm. On the third day the arm was swollen and painful to the touch. Dressing on the fourth day revealed crepitation along the radial side of the forearm, with bubbles of gas escaping from the suture line. There was bronzing of the tissues around the elbow and a putrefactive odor to the arm. Multiple bullae were present on the skin of the forearm. The fingertips were cold and pale (fig. 1). The patient was toxic and in great pain, with a temperature of 103 F.

All sutures were removed, smears of exudate made and a blood culture was taken. *Cl. welchi* and beta-hemolytic streptococci were identified from the wound, and blood culture was positive for beta-hemolytic streptococci. Sulfadiazine was immediately

given by mouth, 70,000 units of "gas gangrene antitoxin" given intramuscularly, hot wet dressings applied locally, and a transfusion of 500 cc. of citrated blood administered. The next morning the temperature had dropped a little, he appeared less toxic, and his blood culture had become negative. His arm had definitely become worse, however, and the edema appeared to have spread to the axilla, while crepitation could be noticed in the upper arm and shoulder. One hundred thousand units of sodium

Fig 2—Appearance of stump the day after surgery and penicillin. The gloved finger is placed in the lateral skin flap. The exposed biceps muscle is viable.

penicillin was given in 100 cc. of isotonic solution of sodium chloride intravenously, 500 cc. of citrated blood was given and a guillotine amputation was done under cyclopropane anesthesia. At operation, the skin and fascia of the stump were split longitudinally and left open. Swabs taken from this area at operation showed gram positive bacilli and gram positive cocci, which on culture proved to be *Cl. welchi* and beta-hemolytic streptococci. Powdered calcium penicillin, 100,000 units, was sprinkled dry into the stump, Dakin tubes were inserted, the stump was bandaged and sealed with cellophane, and a continuous local drip of 1,000 cc. of isotonic solution of sodium chloride containing 100,000 units of calcium penicillin started.

The next morning the wound was dressed. The exposed muscle was clean. A culture taken from the wound showed only a scant growth of diphtheroid organisms. No *Cl. welchi* or beta-hemolytic streptococci were found (fig. 2) on smear or culture.

Fig 3—Temperature, pulse and respiration during the first week in the hospital. Notice the sharp drop in temperature and pulse rate following penicillin and amputation.

The clinical course postoperatively was uneventful except that a thrombophlebitis developed at the site of the intravenous penicillin therapy. The stump now has a pyocyanus infection from ward contamination, but healing is assured. The patient still has a low fever, 99 F., but the stump is ready for skin grafting. Figure 3 shows the temperature, pulse and respiration curves during the first week in the hospital.

SUMMARY

Of 2 cases of *Cl. welchi* infection, 1 was treated locally with calcium penicillin and the other systemically with sodium penicillin and locally with calcium penicillin. Careful bacteriologic studies showed persistence of *Cl. welchi* in the case of cellulitis treated with calcium penicillin locally, while the use of penicillin systemically and locally, combined with guillotine amputation, caused the disappearance of beta-hemolytic streptococcus and *Cl. welchi* from the spreading infection. After oral sulfadiazine, beta-hemolytic streptococci could not be recovered from the blood stream. It must be emphasized that good surgery was the deciding factor in the second case and that penicillin is of most benefit when used in conjunction with good surgical principles.

A PRIMIPARA WITH DIABETES AND MILD TOXEMIA
TREATED SUCCESSFULLY WITH DIETHYL-
STILESTROL

BYRON D. BOWEN, M.D., BUFFALO

The wide experience of Priscilla White¹ in the study of the chorionic gonadotropic hormones and the effect of the use of the estrogens and progesterone in the treatment of pregnant diabetic patients, on whom an increase of these hormones was found, is more than suggestive that their use reduces the incidence of, and is effective in, the treatment of preclampsic toxemia of pregnancy and thereby reduces the fetal and maternal mortality.

The nature of this action is not understood, nor is the metabolism of the estrogens. It may be that the estrogenic substances have a "salutary" effect on the liver. It has been demonstrated that pregnant women can tolerate large amounts of estrogens. Among the possibilities of this beneficial effect are the inhibition of the diabetogenic hormones of the pituitary, the reduction of the rate of glycogenolysis or the removal of antagonistic insulin action, as White's cases have shown that insulin could usually be reduced after the administration of the estrogen. The following case demonstrates this relationship to a high degree:

REPORT OF CASE

History.—Mrs. E. F., aged 23, admitted to the diabetic service of the Buffalo General Hospital Oct. 7, 1943 and discharged Jan. 9, 1944, was referred by Dr. Raymond May, Alden, N. Y. The diabetes was discovered in 1932; she had taken insulin since that time. Because of considerable variation in weight and insulin dosage it was suspected that the control of the diabetes had not been accurate much of this time. She had been in various hospitals on several occasions for adjustment of the diabetic regimen. One of these admissions, at the age of 15, was because of diabetic coma. She had had an enlargement of the thyroid gland since the age of 10. At the time of admission the insulin dose was 90 units of the protamine zinc and 10 to 20 units of the unmodified before breakfast. Her last menstrual period was March 17, 1943. Since the onset of the pregnancy she had experienced some loss of appetite, headache and periods of weakness. For several weeks before admission she had rather frequent attacks of what she thought were insulin reactions—palpitation, sweating, shortness of breath and a choking sensation.

Physical examination showed the following positive findings: diffuse but slight enlargement of the entire thyroid gland; slight accentuation of the basal heart sounds, especially on the aortic side; blood pressure 118 systolic, 82 diastolic; pulse rate 120 to 130; seven months' pregnancy. She was on the whole cheerful, but there appeared to be quite violent mood swings, when she became quite depressed.

Course.—Shortly after admission she began to have attacks of "insulin reactions"; blood sugar determinations made during these attacks were always elevated, and orange juice failed to relieve them quickly. These "spells" were always associated with tachycardia, and during one attack her pulse rate rose to 180. Two electrocardiograms taken two and five days after admission showed a normal sinus rhythm with a rate of 116

and 138 respectively, negative T_s and a tendency to right axis deviation. It then came to our attention, from the Social Service Department, that her husband, who had been in the army forces, was missing several months. It seemed probable that these alleged "insulin reactions" were, in all probability, anxiety attacks. She was seen in consultation by Dr. Mabel Ross from the Psychiatric Department, who concurred in the nature of the attacks. However, Dr. Ross believed that the patient's failure to accept the diabetes and her inability to live as other people did was also a contributing factor. No further attack occurred after their nature was carefully explained to the patient and she had been assured that she would get along all right. On October 15, one week after admission, slight pretibial edema was first noted. There was no essential change in the blood pressure. The urine continued to be free of albumin and abnormal elements in the sediment.

On November 1 she had her first attack of diarrhea. These attacks continued several times each week—often as many as eight watery evacuations daily. These disappeared with the other evidences of toxemia. Several stools showed no occult blood. Culture of the feces was negative for pathogenic enteric organisms.

On November 23 the first trace of albumin in the urine was reported. This persisted and reached a 2 plus reaction by December 8.

On November 4 her blood pressure, which had been measured twice daily, showed its first conspicuous rise: 144 systolic, 84 diastolic; it continued to be essentially in that zone save for an occasional normal or rare higher reading until the toxemia improved.

On admission her red blood cells numbered 4,100,000, with 13.5 Gm. of hemoglobin per hundred cubic centimeters of blood. The white cells numbered 11,000, with 8 per cent bands, 56 filaments, 2 eosinophils, 30 lymphocytes and 4 monocytes. A slight anemia was first noted on November 18, when the red cells dropped to 3,500,000, with 9 Gm. of hemoglobin per hundred cubic centimeters. The leukocytes dropped to 7,900 per cubic millimeter, with no essential change in the differential. On November 26 the red blood cells numbered 3,660,000, with 11 Gm. of hemoglobin.

Two of our enterprising and interested clinical clerks, Mr. Melvin N. Wood and Mr. Paul J. Wolfgruber, determined the serum chorionic gonadotropic hormones on November 11. They were found to be at least 500 rat units per hundred cubic centimeters of blood. This was repeated again on November 26. Then one rat, which had a dose of serum corresponding to 1,700 rat units per hundred cubic centimeters, showed a corpus luteum, but the other rat, which received an amount corresponding to 1,000 rat units per hundred cubic centimeters of blood, showed no corpora lutea macroscopically. Just before her delivery an attempt was made to estimate the blood serum chorionic gonadotropic hormones. Unfortunately this was indeterminate.

On December 1 the patient was given diethylstilbestrol 2 mg. three times a day in the hope that it would alleviate the toxemia. Her weight, which had steadily increased from 58 Kg. (127½ pounds) on admission, had by this time reached 67 Kg. (147½ pounds). Coincident with the use of the diethylstilbestrol there was a prompt and gradual loss of weight with conspicuous diuresis, so that the weight was reduced to 62 Kg. (137 pounds) by the time of delivery on December 17. Also the systolic blood pressures were definitely lower, but the diastolic remained in the neighborhood of 90.

From the beginning the diabetes was difficult to manage. Except for the first two weeks, when the carbohydrate content in her diet was changed back and forth several times from 180 Gm. of carbohydrate to 140 Gm., her diet remained constant all through the observations at 160 Gm. of carbohydrate, 80 Gm. of protein and 110 Gm. of fat. A combination of protamine zinc insulin 90 units and unmodified insulin 30 units resulted in continuous glycosuria up to as high as 50 Gm. daily. An equal number of units of the unmodified insulin given in three doses—morning, evening and midnight—gave somewhat better control, but as the toxemia became more apparent this had to be increased gradually until the patient was receiving 90 units before breakfast, 68 before supper and 68 at midnight by December 1, when the diethylstilbestrol was started. The fast-

From the Buffalo General Hospital and the University of Buffalo School of Medicine.

ing blood sugar on November 29 was 250 mg. per hundred cubic centimeters. Promptly after the administration of diethylstilbestrol, hypoglycemic reactions, which had not been present before, followed—fifteen in eleven days; in three of these, concentrated dextrose solution had to be given intravenously. This occurred in spite of the sharp reduction of the insulin dosage. The reactions did not cease until the dose had been lowered to 44 units in the morning, 30 units before supper and 10 units at midnight. It is interesting that there were but a few grams of dextrose in the urine even after the administration of 50 cc. of 50 per cent dextrose intravenously.

She was delivered on December 17 by Dr. Clyde Randall. Both her labor and her delivery were uneventful. She had an episiotomy. Caudal and chloroform anesthesia were used. Her blood pressure taken during labor was 120 systolic, 80 diastolic on one occasion and 128 systolic, 90 diastolic on another. The weight of the male fetus was 7 pounds 7 ounces (3,570 Gm.).

She required only slightly less insulin after delivery than she had previously: 36 units before breakfast, 16 before supper and 10 units at midnight.

She was discharged on a regimen of 180 Gm. of carbohydrate, 90 Gm. of protein and 120 Gm. of fat with 90 units of protamine zinc insulin and 16 of the unmodified insulin before breakfast. There was slight glycosuria occasionally during the day. Her fasting blood sugar was 182 mg. per hundred cubic centimeters. She had no insulin reactions.

SUMMARY

A primipara who was severely diabetic and who had had diabetes for twelve years was studied in the hospital for a period of three months.

The development of mild toxemia of pregnancy was observed—edema, albuminuria, diarrhea, mild hypertension and anemia. During this period the insulin requirement was nearly doubled. The chorionic gonadotropic hormones exceeded 500 rat units per hundred cubic centimeters of blood.

Soon after the oral administration of diethylstilbestrol 6 mg. daily the symptoms and signs of the toxemia disappeared, and the insulin dosage had to be promptly reduced because of the occurrence of many insulin reactions. At that time an estimation of the chorionic gonadotropic hormone was, unfortunately, indeterminate.

100 High Street.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports.

HOWARD A. CARTER, Secretary.

KREISELMAN RESUSCITATOR BELLOWS TYPE, MODEL 110, ACCEPTABLE

Manufacturer: The Ohio Chemical & Manufacturing Co., 1177 Marquette Street, Cleveland.

The Kreiselman resuscitator is designed to administer artificial respiration to all except the newborn. In general the apparatus as marketed consists of a bellows having an air and oxygen intake valves, an exhaust and a relief valve, a handle, an elbow connector for the face mask, an airway and a carrying case.

OPERATION

Administration of the air or air-oxygen mixture is accomplished by applying the mask over the patient's nose and mouth in airtight fashion and manually expanding and compressing the bellows. With the patient in the prone position, the head is turned slightly resting on the patient's hand as when using the prone pressure method of manual artificial respiration. When the patient is in the prone position the resuscitator is used with an elbow interposed between the exhaust valve of the bellows and the mask.

The oxygen intake valve has an inlet nipple to which a supply tubing for oxygen is attached. The valve is large enough to admit sufficient oxygen under pressure for therapeutic purposes. When the resuscitator is used with air only, this valve remains closed. The relief valve on the bellows operates at an internal

pressure of 14 to 15 mm. of mercury and discharges freely the contents of the bellows at a pressure of 25 mm. of mercury.

The technic of operation is as follows:

1. Clear the mouth and throat of mucus and remove any foreign bodies from the mouth. Use a clean handkerchief or cloth if an aspirator is not available.
2. Place patient on back with hand extended, then carefully insert tip of airway above tongue along roof of mouth until the airway is well behind tongue thus holding it forward.
3. Keep chin raised.
4. Place mask over nose and mouth and hold it on airtight with one hand.
5. Operate bellows with other hand as follows:
 - (a) Place the hand palm down under strap handle and raise bellows until filled with air.
 - (b) Press down to compress the bellows until chest wall rises.
 - (c) Release pressure at once by raising (expanding) the bellows.
 - (d) Repeat this procedure of expanding and compressing the bellows at the rate of 18 times per minute.
 - (e) When the patient makes breathing efforts, compress the bellows as he breathes in.
6. When resuscitation is attempted with the patient on his side or abdomen, turn the head to the side and use the bellows with the mask-elbow.
7. To use oxygen, attach supply tube to inlet valve on the bellows.

INVESTIGATIONS

One physician having had experience with this device reported that it was tested on a number of dogs that were asphyxiated. Controlled experiments were run using other kinds of mechanical apparatus for production of artificial respiration and also manually controlled appliances which are attached to anesthetic apparatus. The Kreiselman bellows type resuscitator was found to be as efficient as any of the other apparatus tried. The same physician said that the bellows resuscitator had been used successfully on 12 patients, all of whom had experienced respiratory arrest by inhalation of anesthetic agents. He reported that (1) asphyxia was not present in any of these cases, (2) all of the 12 patients were successfully and efficiently revived with the bellows type apparatus, (3) none of the patients died, (4) respiratory arrest in these patients was produced by an overdose of an anesthetic agent for the expressed purpose of testing the apparatus and (5) no impairment to the patient's lungs was noted either immediately or later.

The Kreiselman (bellows type) apparatus together with the evidence submitted with it by this firm was referred to the Council investigator for examination and report. He stated that the device was used over a considerable length of time on patients purposely prepared for trial by stopping their respiration. The apparatus does what it is expected to do; namely, inflates the lungs with either air or oxygen under moderate positive pressure. The maximum pressure is controlled by a safety valve and is set to open long before dangerous pressures are reached.

The manufacturer expressed a desire to supply this apparatus to police and fire departments and other lay organizations that perform emergency artificial respiration on victims of drowning, gas poisoning, electric shock and so on. The firm was asked to submit reports of cases of asphyxia in which the device has been used successfully by lay operators in emergency cases. The firm replied that it was collecting these data but to date did not have enough records to satisfy the Council requirements.

The Council on Physical Medicine voted to accept the Kreiselman resuscitator for use in operating rooms and in medical institutions under the direction of a physician but voted not to accept it for use by lay organizations, because evidence is not available that a layman has successfully resuscitated an asphyxiated person with it.

Bellows resuscitator.

THE FISCHER CRYSTAL SHORT WAVE DIATHERMY APPARATUS, MODEL VC, ACCEPTABLE

Manufacturer: The H. G. Fischer Company, 2323-2345 Wabansia Avenue, Chicago 47.

This apparatus applies heat to the tissues of the body for the treatment of disease. Where heat is indicated as a therapeutic measure, this appliance may be used. So far as it is known the immediate and only effect of medical diathermy is the production of heat, and the physiologic effects are those which normally follow the production of heat in the living tissues. This medical diathermy apparatus is built to meet not only the requirements of the Council on Physical Medicine but the requirements of the Army Medical Corps as laid down in the Federal Standard Stock Catalogue, section IV, part 5.

Model VC is a so-called crystal controlled apparatus. The frequency, 13,660 kilocycles per second (21.95 meter wavelength), does not, according to reliable evidence, vary from the norm more than 0.05 per cent; in fact, the tolerance of frequency stability is much less, and this under wide temperature and humidity variations.

The generator consists of a steel cabinet with an enamel finish, a steel chassis which may be removed and a control panel mounted to the chassis with all controls thereon. The chassis consists of three units; namely a crystal control, a buffer and a final amplifier. The crystal control and buffer compartment may be removed from the chassis for repair or replacement by removing a screw at the base clamp of the buffer compartment. When the crystal is removed, the entire generator is disconnected from the power supply. An overload switch is also provided to protect the unit against short circuits. Connections for treatment electrodes are provided at the side of the unit. Treatment is applied by means of a cable or drum. It weighs approximately 200 pounds.

The ability of the apparatus to heat tissue was tested in a laboratory acceptable to the Council. The report is as follows:

The method followed was: 3 turns of cable around thigh, overall measurements 7 to 8 inches, one hand towel and $\frac{3}{8}$ inch layer of felt between cable and skin. Skin hyperemia was observed.

TABLE 1.—Cable Technic

Experiment Number	Deep Muscle Initial	Temperature of Final	Oral Temperature, F.	
			Initial	Final
1.....	97.1	106.5	98.3	99.0
2.....	97.4	106.2	98.3	99.2
3.....	97.4	107.0	98.3	99.5
4.....	97.5	104.9	98.6	99.7
5.....	97.6	104.7	98.8	99.8
6.....	97.6	105.4	99.0	100.0
Average.....	97.4	105.8	98.5	99.5

TABLE 2.—Disk Technic

Experiment Number	Deep Muscle Initial	Temperature of Final	Oral Temperature, F.	
			Initial	Final
1.....	97.0	104.2	98.5	98.4
2.....	97.6	104.3	98.4	98.7
3.....	97.3	104.0	98.5	98.8
4.....	97.7	105.5	98.8	99.1
5.....	97.8	105.5	98.8	99.4
6.....	97.8	105.0	98.9	99.5
Average.....	97.5	104.9	98.6	99.0

The method followed for the disk technic was: 10½ inch diameter disk applied obliquely to the thigh with one layer of toweling between surface of disk and the skin, center of disk opposite center of cannula. Blebs were produced as the result of point heating.

Heating-load test reveals that the transformers meet the requirements of the Council. The report from a laboratory recognized by the Council as qualified to judge on the frequency stability indicates that the crystal control feature maintains a stability within 0.05 per cent.

The apparatus operates on 115 volts alternating 60 cycle current. The lamp load test shows an output of 200 watts. On practical test the apparatus proved to stand up well when used clinically.

The Council on Physical Medicine voted to accept the Fischer Crystal Short Wave Diathermy apparatus, Model VC, for inclusion in its list of accepted devices.

Council on Foods and Nutrition

The following report, authorized by the Council for publication, represents the completion of the study of the nutritive value of prepared cereal foods made under a grant of the Board of Trustees at the request of the Council.

GEORGE K. ANDERSON, M.D., Secretary.

VITAMIN CONTENT OF PREPARED CEREAL FOODS

GEORGE KITZES, Ph.D.

AND

C. A. ELVEHJEM, Ph.D.

MADISON, WIS.

A preliminary report on the thiamine, riboflavin and niacin content of a number of prepared cereal products was published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Dec. 4, 1943. More extensive data are tabulated in the accompanying table. Some new products have been included, but the main purpose of the additional work was to determine the variation in the vitamin content of the typical products on the market. The cereals were purchased from grocery stores in different parts of Madison and from stores having a rapid turnover in order to avoid products kept on the shelves for long periods of time. Most of the samples were obtained at three different periods, spring, summer and fall of 1943. The thiamine was determined by the thiochrome method¹ and the riboflavin and niacin by microbiologic procedures.²

The values for whole grains are included again for comparison. The products to which restorative additions of synthetic vitamins or vitamin concentrates have been made are indicated with an asterisk. Others enriched according to proposed federal standards of enrichment are appropriately indicated. When the individual samples gave values within rather narrow limits, one average figure is given; when a greater variation was observed, the range of figures is included.

The variation between samples of the same product purchased at different periods is surprisingly small. The restored and enriched products gave the most variable results, owing undoubtedly to the higher vitamin content and to difficulties in obtaining uniform distribution of the added vitamins. Some of the products low in thiamine also showed considerable variation, probably because of differences in the degree of processing.

It is interesting to note that a large percentage of the wheat products and practically all of the corn, oats and rice products contain levels of thiamine within the range for the whole grains. Very few of the riboflavin values fall below the corresponding minimum whole

ACC. No. 46

grain values. The biggest discrepancy occurs in the niacin values for wheat. Very few of the products, even when the vitamin has been added, meet the minimum values of 5.4 mg. for 100 Gm. The reason for this is readily evident. Wheat bran is very rich in niacin, and the bran is generally removed in the preparation of the wheat products. Further consideration may have to be given this standard, but in any case a product design-

of uniformity in the expression of nutritional values on the package was quite apparent. Some are expressed in terms of the average serving, others as a 1 ounce serving or on a pound basis, giving the percentage of the minimum daily requirements in some cases and in others the milligrams or international units contained therein. It is difficult or impossible for the average person to make an intelligent comparison of the nutri-

Vitamin Content of Whole Grains

A majority of samples of whole grains contain the indicated nutrients in amounts within the following ranges
(Data Compiled by the Food and Nutrition Board, National Research Council)

nated as containing added niacin should contain more than 4 mg. per hundred grams.

In summary it is evident that the cereal manufacturers have made excellent progress in improving and standardizing their products. Sufficient data are now available to allow rather accurate estimation of the amount of thiamine, riboflavin and niacin contributed by most of the commercial products.

In the process of handling the numerous brands of prepared cereal foods which were examined, the lack

tional content of the various cereal products by examining the labels. On the other hand, if these values could be expressed on the uniform basis of the average 1 ounce serving with the nutritional content in terms of percentage of daily requirements as well as actual milligrams (or international units for vitamins A and D) supplied, a better understanding and appreciation by the housewife and nutritionist of the food value of the various types of cereal products would be realized.

SATURDAY, SEPTEMBER 9, 1944

THE CHICAGO VIVISECTION FUROR

For some weeks Chicago has been treated to a spectacle such as only Chicago can furnish, because the self-elected star of the performance is Irene Castle, once noted as half of a terpsichorean team and now maintaining a somewhat aging reputation by periodic appearances in the limelight in behalf of a dog shelter called Orphans of the Storm and in behalf of a general attack against all experiments with animals. Listed in the supporting cast is Mr. William Randolph Hearst of California and New York, who places the *Chicago Herald American* and all its staff at Miss Castle's disposal during the run of the play. Fortunately for the American people and fortunately also for the scientific medical institutions of Chicago, every other newspaper in the city has recognized the menace of the Castle-Hearst combination and has come to the support of the Chicago leaders of medical education with the amount of space and the vigor demanded by the antivivisectionist shrieking. The pity of it all is that so much important space and time should have to be devoted in the war effort to meeting this stupid and obsolete sentimentalism.

The City Council of Chicago a good many years ago passed an ordinance that makes available the use of stray dogs for scientific medical study. Apparently some of the aldermen have been high pressured by Mr. Hearst's campaign into introducing an amendment to the city code which would make it difficult or impossible for medical science to get the necessary number of dogs to carry on. Specifically, it proposes to repeal the ordinance under which stray dogs in the city pound go to medical schools because their owners fail to reclaim them after five days.

The campaign of the *Herald American* featured what was said to be the eye witness story of a former employee of the medical school of the University of

Chicago. This man had served as an animal caretaker for only six weeks and left his position without notice just a few days before the first article appeared in the *Herald American*. Apparently he had used his time to take pictures surreptitiously—pictures which were harmless in themselves but which were made to appear brutal and improper by the captions printed under them. The evidence is positive that the laboratories in question utilize animals with the utmost discrimination, without subjecting them to unnecessary pain or discomfort, carrying out all operative experiments under anesthesia and in accordance with the same standard of procedure that is used in hospitals everywhere throughout the country. The attack was centered on Dr. Dallas B. Phenister, professor of surgery, whose character and reputation as a distinguished scientist need no defense. The fact that the attack would be centered on a surgeon of distinction for his scientific accomplishments and his devotion to the healing of disease is an indication of the stress to which the antivivisectionists were put in order to make any kind of case whatever. Opposed to the ridiculous presentation which the antivivisectionists made before the city council were the professors of physiology in all the medical schools, the statements of the Surgeons General of the Army, Navy and U. S. Public Health Service and the personal appearance of Major General George F. Lull, Deputy Surgeon General of the Army. The incident served to bring out the tremendous advancement that medical science has made in recent years, largely by the use of animal experimentation. Long since and repeatedly it has been emphasized that dogs themselves have benefited, as well as has man, by the very experimentation that this illogical group condemns.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION wishes to commend the medical scientists of Chicago for having given so much of their time and their energy to meeting this challenge. The preparation which they made for the hearings before the city council, with the attendance of all the medical students of the city in uniform at the sessions, the orderly and painstaking presentation of the case, may well be models for similar efforts when a similar challenge happens to arise elsewhere in the nation or even in Washington. Yet it all comes down to a paragraph from a statement in an editorial in the *Chicago Tribune*, which gave many columns to interviews and editorials during the weeks preceding the hearing.

The *Tribune* said:

There comes a time when patience with people like this ceases to be a virtue. It is no excuse to plead for them that they are sincere. So, probably, is Hitler, who is no crazier than some antivivisectionists.

STREPTOTHRICIN

In 1941 Waksman of the New Jersey Agricultural Experiment Station isolated a bactericidal substance from a soil streptothrix (*Actinomyces lavendulae*), which he named "streptothricin."¹ Streptothricin is completely adsorbed on charcoal from a fluid culture medium from which it can be recovered by treatment with dilute acid. Waksman found that the crude product thus prepared had a definite inhibitory action on the majority of the bacterial species he tested. As little as 0.1 mg. of the product added to 10 cc. of nutrient agar completely prevented the growth of *Escherichia coli* and many other gram negative bacteria. Gram positive bacteria were of variable resistance, some being extremely sensitive to this bacteriostatic agent while others were highly refractory. Streptothricin also had a decisive antibiotic action against numerous fungi and yeasts.²

A preliminary report on the therapeutic efficiency of this bacteriolysin has been made by Robinson and his associates³ of the Merck Institute for Therapeutic Research, Rahway, N. J. The crude streptothricins tested by these investigators varied in potency from 5 to 300 units per milligram, the unit being the minimum quantity of the crude product which added to 1 cc. of nutrient broth completely inhibits the growth of a selected strain of *E. coli*. The toxicity of these products was tested by administering a single dose intravenously, subcutaneously or by mouth to each of a selected group of 10 mice. Mice given as much as 30,000 units per kilogram of body weight intravenously, 60,000 units subcutaneously or 250,000 units orally showed no evidence of toxicity. When twice these doses were administered, anorexia accompanied by a gradual loss of weight was noted in most of the mice, with a 20 per cent mortality.

Confirming Waksman's data, the bacteriostatic titers were determined by incorporating various amounts of each product in melted blood agar and streaking the surface of the solidified agar with a variety of pathogens. The minimum amount of streptothricin necessary for bacteriostasis varied with different bacterial species. *Eberthella typhi* was completely inhibited by as little as 4 units of streptothricin per cubic centimeter, while *Escherichia coli*, *Staphylococcus aureus*, *Salmonella schottmülleri*, *Diplococcus pneumoniae*, *Bacterium flexneri* and certain strains of *Streptococcus haemolyticus* required from 16 to 32 units. *Streptococcus viridans* and *Streptococcus lactis* were refractory, 1,024 units giving only partial growth inhibition. Intermediate groups included several strains of *Streptococcus haemolyticus*, *Staphylococcus aureus*, *Neisseria meningitidis*, *Proteus vulgaris* and *Aerobacter aerogenes*.

Therapeutic tests were made on groups of 30 to 60 mice. Each mouse was inoculated intraperitoneally with 10,000 lethal doses of a selected pathogen. Treatment was begun immediately after inoculation. The therapy consisted of either a single or a repeated dose of streptothricin given intravenously, subcutaneously or by mouth. A single dose of 50 to 100 units (a tenth of the toxic dose) given subcutaneously shortly after inoculation apparently affords complete protection against *Salmonella schottmülleri*, *Escherichia coli* and *Bacterium shigae*, while 3,000 units was required for the same therapeutic effect if the drug was given by mouth. With relatively refractory micro-organisms, such as *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Diplococcus pneumoniae*, practically no beneficial effects were noted, even when the dose was increased tenfold, i. e. approaching the toxic range. It was also noted that streptothricin given by mouth reduces the normal lactose fermenting flora of the gastrointestinal tract.

Robinson suggests that in time streptothricin may prove to be of value in the treatment of bacillary dysentery, typhoid and colon infections. If so, it would function as a valuable supplement to penicillin, which has little or no therapeutic action against these gram negative infections.

ABORTIVE OR NONPARALYTIC
POLIOMYELITIS

Fortunately the most frequent clinical form of poliomyelitis is the abortive or nonparalytic. Similar transitory infections may occur in the experimental disease in monkeys. In both cases the absence of paralysis is not necessarily due to failure of the virus to invade and multiply in the tissues of the central nervous system but to limitation of its spread therein. The limitation may depend on the virus, on the host or on both. Faber, Silverberg and Dong¹ studied the resistance to a strain of virus of the cynomolgus monkey under well controlled experimental conditions. They found that nontraumatic exposures to the virus of the respiratory and alimentary mucous membranes of cynomolgus monkeys may be followed by a definite resistance to later intracerebral inoculations of the virus. In such cases typical lesions were found in the central nervous system descending from the level of the inoculation into the brain stem and to a much more limited extent into the cord. There were no indications of any invasion of the central nervous system previous to the intracerebral inoculation, but lesions were found in the peripheral ganglions corresponding to the mucous membranes previously exposed to the virus.

This limitation of spread of experimental poliomyelitis in monkeys resembles the stop in the evolution of human poliomyelitis which results in the clinical gradations represented by abortive, nonparalytic and mildly paralytic forms of the disease. It may be assumed that natural exposures to the virus lead to increase in the resistance to its invasion of the central nervous system, possibly due to the development of specific antibodies. Whether natural human exposures to the virus which do not result in clinical poliomyelitis may leave lesions in peripheral ganglions, as was the case in the experiments on monkeys, is a question. Post-mortem study of these ganglions, especially in children, with this question in mind might well be worth while.

At present there seems to be no practical way of increasing successfully the resistance to human poliomyelitis by artificial means. Previous efforts to that end led to the conclusion that the injection of killed virus is not effective. A safe method of immunizing with modified living virus has not yet been found.

AIR BORNE POLIOMYELITIS

The epidemiology of human poliomyelitis has recently directed attention largely to the presence of the virus in feces and sewage and to the growing conviction that infection with poliomyelitis virus is usually by way of the alimentary tract. The demonstration by Faber and his associates¹ of Stanford University of the ease with which the upper portions of the alimentary tract of monkeys can be penetrated by the virus has intensified this concept. A modification of this belief will presumably follow recent studies of the virus content of nasopharyngeal secretions of clinical cases and attempts to infect experimental animals with air borne virus. Up to five years ago, out of 287 clinical trials the virus of poliomyelitis had been isolated but 29 times from the human nasopharynx.² Paul³ concluded from such data that less than 6 per cent of the poliomyelitis patients had viable virus on the nasopharyngeal surfaces, an insignificant percentage when compared with the great frequency with which the same virus is present in the stools or colonic washings in clinical cases.

A different perspective is suggested by a resurvey currently reported by Howe and his associates⁴ of Johns Hopkins University. Howe discarded the nasopharyngeal irrigation technic of earlier investigators and obtained secretions from the posterior wall of the oropharyngeal surface and the peritonsillar areas by means of cotton swabs. The two swabs used with each

patient were detached, dropped into 1 cc. of sterile water and stored on solidified carbon dioxide. The two swabs were afterward eluted in phosphate buffer solution and the fluid pressed out or sucked out by a syringe. The resulting fluid was rendered bacteriologically sterile by a thirty-six hour contact with a quarter volume of ether, after which the ether was removed. The yield was usually 1.1 cc. of fluid from each patient. The entire specimen was inoculated intracerebrally into a rhesus monkey, half of the sample being injected into each lateral thalamus. This region was chosen because of its relatively high susceptibility to the virus and because its deep position minimized the danger of leakage or backflow.

Specimens have been tested from 14 random cases of juvenile poliomyelitis, all tests being made during the first week of the disease. Of this group 7 specimens produced typical and usually lethal poliomyelitis in rhesus monkeys, the positive results being equally distributed between paralytic and nonparalytic human cases. If fully confirmed, this high percentage would suggest that nasopharyngeal secretions play a much more important role in the spread of poliomyelitis virus than had been previously concluded. Many human cases would presumably be due to air borne droplet or dust infection.

This suggestion is made highly plausible by studies of the infectivity of air borne poliomyelitis virus, currently reported by Faber and his associates⁵ of Stanford University. The Stanford experimenters used an improved atomizing flask into which a virus suspension can be delivered as a fine spray. All unevaporated droplets are retained in the flask and an even suspension of dry droplets or "droplet nuclei" passed into a large respiratory chamber. This chamber accommodates the heads of 4 monkeys under anesthesia with pentobarbital sodium. After one hour exposure to the virus infected air 5 of the 7 rhesus and 6 of the 7 cynomolgus monkeys thus far tested developed typical poliomyelitis. Histologic evidence indicated that the virus had entered the central nervous systems of all 11 monkeys through the olfactory nerves. To study other possible respiratory ports of entry the test was repeated on 35 rhesus and 10 cynomolgus monkeys in which olfactory blockade had been induced by previous application of 1 per cent zinc sulfate. Of these, 2 rhesus monkeys and 4 cynomolgus monkeys developed typical poliomyelitis. Serial sections indicated that the non-olfactory port of entry was in most cases through the afferent fibers of the fifth cranial nerve, entrance by way of the local sympathetic fibers being demonstrated in but 1 case.

Faber concludes from these tests that the concept of poliomyelitis as an air borne disease acquired by inha-

lation of contaminated air or dust deserves more consideration. Such a view, he emphasizes, does not exclude ingestive infection, since experiments have shown that in monkeys infection occurs with equal ease by the two ways. Which mode of infection is the more important for man is a problem that still awaits solution.

MALNUTRITIONAL ANTIVIRAL IMMUNITY

Reasoning from experimental evidence obtained from a study of bacterial infections, many clinicians have assumed that resistance to pathogenic viruses would be lowered as a result of dietary deficiency and that prophylactic effects would follow the administration of corrective doses of such factors as ascorbic acid, thiamine, riboflavin, nicotinic acid and pantothenic acid. This line of reasoning was challenged in 1939 by Foster and his associates¹ of the department of pediatrics, University of Pennsylvania School of Medicine, who studied the effects of thiamine deficiency on resistance to poliomyelitis virus.

Litters of white mice varying from 21 to 31 days of age were split into two groups. One group was fed ad libitum a standard diet containing 100 micrograms of thiamine per hundred grams. The second group was placed on a similar diet in which the thiamine content had been reduced to 10 micrograms per hundred grams. Fifteen to twenty days later each mouse was injected intracerebrally with 0.03 cc. of a 0.5 per cent suspension of virus infected mouse brain (Lansing strain), control injections being made with 0.5 per cent suspension of normal mouse brain. Typical paralysis was noted in 74 per cent of the mice at the optimum thiamine level, as contrasted with but 13 per cent paralysis in the thiamine deficient group.

With a third group of mice the thiamine content of the ingested food was raised to 30 micrograms per hundred grams (minimum maintenance level). In this group 17 per cent of the injected mice developed paralysis. The conclusion was drawn that even a partial reduction in optimum thiamine intake increases resistance to poliomyelitis virus. Foster² subsequently found that mere restriction of caloric intake without reduction in ingested thiamine resulted in a similar though less definite increase in resistance to poliomyelitis.

These results were afterward confirmed by Rasmussen and his associates³ of the University of Wisconsin, who tested four carefully selected mouse groups. The first group was fed a synthetic diet containing optimum amounts of all necessary food factors except thiamine. On this diet the mice developed an acute deficiency, characterized by rapid loss of weight. A

second group of mice was fed the same diet plus a minimum maintenance amount of thiamine (30 micrograms per hundred grams), on which diet the weight remained constant for at least thirty days. A third group was fed the same diet plus an optimum amount of thiamine (200 micrograms per hundred grams). On this diet the weight increased rapidly. A fourth group was fed an excessive amount of thiamine (600 micrograms per hundred grams). Thirteen days after the animals had been placed on these diets each mouse was injected intracerebrally with 0.03 cc. of a 2 per cent brain-cord suspension of the Lansing mouse adapted poliomyelitis virus. Within fourteen days 81 per cent of the mice at the optimum or excessive thiamine level developed paralysis, while but 14.2 per cent of those on the thiamine free diet became paralyzed. Of those at the minimum maintenance level 50 per cent became paralyzed.

Rasmussen also tested a fifth group of mice in which there was a restricted caloric intake without a reduction in the thiamine or other vitamin factors. The control morbidity of 81 per cent was reduced to 65 per cent in this group. The Wisconsin bacteriologists then broadened their field of research to include tests with Theiler's encephalomyelitis virus injected intraperitoneally. Here the differences in resistance were of the same order but less pronounced than with poliomyelitis virus, the control morbidity of 55 per cent being reduced to 42 per cent as a result of thiamine deficiency. The field of research was then widened to include the effects of restricted intake of pantothenic acid.⁴ They found that Swiss mice fed a synthetic ration deficient only in calcium pantothenate exhibited a definitely increased resistance to Theiler's encephalomyelitis virus. There was, however, little or no increased resistance to poliomyelitis virus.

A theory to account for this malnutritional antiviral immunity was suggested in 1942 by Sprunt⁵ of Duke University, who studied the resistance of undernourished rabbits to intradermal injection with vaccinia virus. In all cases the resulting lesions were fewer and smaller in the malnutrition group than in adequately fed controls. Sprunt interpreted this as evidence that vaccinia virus is less able to multiply in poorly nourished tissue cells than in adequately nourished cells. With this theory a malnutritional hypersusceptibility to bacterial infections coupled with a partial malnutritional immunity to virus diseases ceases to be paradoxical.

Sprunt's theory is based on the classic assumption that the virus particle is a living parasite feeding on or in competition with the invaded tissue cell. A more complex theory would be necessary if the virus was pictured as a giant protein molecule multiplied by the engrafted cell.

Current Comment

POSTWAR TRAFFIC DANGERS

Automobile traffic hazards will no doubt begin to increase almost at once after the end of the war. Methods to control this problem should receive careful consideration now. The National Safety Council has just published an excellent brochure on postwar traffic problems for a group of forty sponsoring organizations, including the American Medical Association. According to this booklet the long-term problems will include greater traffic volumes and speeds, probable changes in traffic and parking patterns, new developments in automobile design, continued if not increased night traffic hazards, and no anticipated decrease in the accidents resulting from drinking alcoholic beverages. Safety measures devised and instituted, although unevenly, before the war must be continued and implemented. Especially important will be training of adequate personnel to meet the new and perhaps unexpected problems which will surely arise. New measures must be introduced to cope with new problems. Road construction, betterment of existing streets and highways, and traffic engineering administration will play a part in preventive measures. New technics will have to be devised for police personnel and their equipment; standard technics of enforcement can be more widely adopted. Vehicle inspection, driver licensing, traffic safety instruction and education are additional measures which will require careful application. About 35,000 deaths and well over a million injuries annually from automobile accidents were recorded during recent prewar years; all evidence indicates that this cause of death and injury will rise to new heights in the postwar period unless adequate preventive measures are taken.

BIOLOGIC SYNTHESIS

The older view, championed by Liebig, considered that the chemistry of the animal body was destructive in character, whereas in plants widespread synthesis took place. Subsequent investigation has shown the fallacy of this concept; there is ample evidence that fat and carbohydrate are synthesized from unlike precursors, while purines, hormones and aminoacetic acid, among other compounds, are known to be products of biochemical synthesis in the animal body. The most recent evidence on this general point relates to beta-alanine, a nitrogenous constituent of the muscle extractives carnosine and anserine. Although alpha-alanine is a common amino acid obtained from most proteins, the beta analogue has been considered a biochemical novelty. Interest in this compound was increased when it was discovered¹ that it constitutes part of pantothenic acid, one of the vitamins of the B group. It becomes of interest to know whether or not the growing animal can synthesize the beta-alanine in its tissues. Using weanling rats, Schenck and du Vigneaud² have shown that the beta-alanine in the nonhepatic tissues increases some twenty times in the fifty days after weaning and

that this increase is independent of the amount of beta-alanine in the diet. As the tissue extractives assume greater importance in the metabolism of muscle—quantitatively the most important tissue in the body—the origin and availability of these compounds becomes of greater interest.

THE HETEROLOGOUS TRANSPLANTATION OF HUMAN CANCERS

Greene and Lund³ have reported successful transplantation of a series of 10 human cancers to the anterior chambers of eyes of guinea pigs. The series contained a fibrosarcoma of the chest wall, an adenocarcinoma of salivary gland tissue, a chondrosarcoma of the larynx, a malignant melanoma, an epidermoid carcinoma of the buccal mucosa, an adenocanthoma of the urethra, a mammary fibrosarcoma, an undifferentiated carcinoma of the lung, and an epidermoid carcinoma of the lung and a chordoma. The transplants grow progressively in the alien host and bear a close microscopic resemblance to the original tumors. In the majority growth became apparent in all successful transplants within several days. In earlier experiments with rabbit tumors the authors failed to transplant benign tumors or tumors in their preinvasive stage. Apparently, therefore, heterotransplantability may be a characteristic property of cancer. More recent experiments demonstrate that in man as well as in rabbit cancer autonomy or transplantability transcends species barriers. Numerous attempts to transfer benign human tumors to lower animals have failed. Transplantation experiments utilizing biopsy tissue from precancerous lesions and from anaplastic tumors during preinvasive stages likewise failed. Transplantability of malignant tumors to lower animals, it is pointed out, may serve as a diagnostic aid in a case of questionable tissues and assist in the morphologic classification of cancers. Cancers may be associated with local tissue reaction that obscures the nature of the cell involved in the neoplastic process. Thus the tissue obtained from the first biopsy of the fibrosarcoma of the chest wall in 1 of their cases contained a large number of giant cell forms and the question of muscular origin arose. However, only the fibroblastic elements survived guinea pig transfer, and it became clear that the growth was fibrosarcoma and that the giant cells were reactive rather than neoplastic in nature. It is also pointed out that transplants often show a slightly higher degree of cellular differentiation and organization than is found in the primary host and thus allow a classification of highly anaplastic tumors. This was demonstrated in their case of transplanted chordoma. The ability to grow cancer in lower animals affords an approach to many other problems associated with human tumors. After successful primary transplantation the cancer can be carried by serial passage to new generations of animals and subjected to a variety of investigations not permissible in the human host. After preliminary growth in the anterior chamber of the eye, transfer to other body regions is readily effected.

MEDICINE AND THE WAR

ARMY

REORGANIZATION OF OFFICE OF SURGEON GENERAL

It has recently been announced from the office of the Surgeon General of the Army that the post of Assistant Surgeon General is to be filled by Brig. Gen. Raymond W. Bliss. The post is newly created as a part of a recent reorganization. General Bliss will hold the new post in addition to his duties as chief, Operations Service.

The Administrative Service is dissolved, as part of the reorganization: the Fiscal, Legal and Office Service Divisions will report directly to the executive officer as previously. In place of the Professional Service, four Professional Consultant Divisions are being created: medical, surgical, neuropsychiatric and reconditioning. All personnel of the Nursing Division, another division to be dissolved, and related aspects of the Army Nurse Corps will be the responsibility of the Army Nurse Branch of the Military Personnel Division, Personnel Service. The overall policy aspects of the Army Nurse Corps will be the responsibility of the newly constituted Nursing Division of the Professional Administrative Service.

A new Professional Administrative Service is being created, with Col. Arden Freer as chief and Col. Esmond R. Long deputy chief. The following will be included: Physical Standards Division, Nursing Division, Medical Statistics Division, Professional Inquiries Unit, Women's Health and Welfare Unit. Col. Florence A. Blanchfield will be director of the Nursing Division, Professional Administrative Services.

SURGICAL OPERATING TRUCKS TAKE HOSPITAL TO WOUNDED SOLDIERS

The Army Medical Department has established mobile surgical groups which provide hospital facilities for wounded soldiers near the front lines. The tent is carried on a two wheel trailer along with an electrical generating unit; the hospital vehicle can be made ready for full operation within thirty minutes. Sufficient room is provided for operating teams composed of surgeons, nurses and technicians, making it possible for 2 men to be operated on simultaneously. The unit is capable of caring for from 80 to 100 men a day. The truck is equipped with a variety of special instruments for orthopedic, nerve, chest, maxillofacial and brain surgery; operating tables, steam and dry sterilizers, lighting equipment, medicines, blood plasma, bandages and dressings, record files, auxiliary power unit, surgical linens and operating gowns.

MAJOR DUNN APPOINTED NEURO- PSYCHIATRIC CONSULTANT

Major William Harold Dunn has been appointed neuropsychiatric consultant for the Fifth Service Command Headquarters, Columbus, Ohio. Major Dunn was instructor in psychiatry at Cornell Medical College and assistant chief of the outpatient department at the Payne-Whitney Clinic in New York City. He has had extensive army experience with hospital units in the South Pacific. Immediately preceding his appointment he was on the staff of the School of Military Neuropsychiatry at the Mason General Hospital. Dr. Dunn graduated from Harvard Medical School in 1927.

NURSES DECORATED FOR GALLANTRY UNDER FIRE

Twelve officers of the Army Nurse Corps have been awarded the Bronze Star for heroic service in Italy, the War Department recently announced. This brings to 17 the number of American nurses who have been decorated for gallantry under fire. One Bronze Star and four Silver Star awards were made earlier.

CANCEL REQUISITION FOR PARASITOLOGISTS

Release FR-208, dated August 10, from the Headquarters Army Service Forces, Washington 25, D. C., states that the files of a sufficient number of qualified candidates have been received to meet the needs of the Surgeon General under requisition 228, parasitologists. This requisition will be canceled and further procurement will close immediately. Papers on candidates already procured and in process will be completed with the exception of WD AGO form 63, if not already accomplished, and forwarded under form OPS-22 with such requisition number shown in proper place.

CHIEF ARMY NURSE OF SIXTH CORPS AREA RETIRES

Lieut. Col. Pearl C. Fischer recently retired as chief of army nurses for the Sixth Service Command and was honored at a dinner at the Gardiner General Hospital, Chicago, August 8. Colonel Fischer was the first woman with that rank to serve with the Sixth Service Command. She will be succeeded by Lieut. Col. Martha Jane Clement, director of army nurses in the Southwest Pacific Area.

MAJOR MARY C. WALKER GIVEN HONORARY DEGREE

The University of Denver recently conferred the honorary degree of Doctor of Humane Letters on Major Mary C. Walker of the Surgeon General's Office. Mr. Thomas A. Dines, chairman of the board of trustees of the University of Denver, stated that "the university is pleased to extend this honor to a member of the nursing profession not only in recognition of her individual worth but as a fine representative of her profession."

SIXTY-NINE ARMY NURSES HAVE DIED IN LINE OF DUTY

The War Department recently announced that of approximately 40,000 members of the Army Nurse Corps 69 have lost their lives in line of duty since Pearl Harbor, 24 have been reported as wounded and 66 are prisoners of war. Six officers of the Army Nurse Corps have died as a direct result of enemy action. Other deaths have been due to vehicle accidents, airplane crashes and disease.

CHICAGO NURSE RECEIVES AIR MEDAL

Lieut. Helen F. Lyon of Chicago, a member of the first overseas flight nurse team, who went to the Aleutian theater last year to evacuate men wounded in the Attu campaign, has recently been awarded the Air Medal. With Lieutenant Lyon's unit when it arrived in the Aleutians was 2d Lieut. Ruth M. Gardiner, who was the first air evacuation nurse to lose her life in this war and after whom the Gardiner General Hospital was named.

FLIGHT SURGEONS' ASSISTANTS

A class of forty flight surgeons' assistants completed the six weeks course in aviation medicine at the School of Aviation Medicine, Randolph Field, Texas, July 29. These men are trained as specialists in assisting flight surgeons in the selection, care and maintenance of the flier. Brig. Gen. Eugen G. Reinartz is commandant of the School of Aviation Medicine.

FRENCH OFFICER CITED BY U. S. ARMY

Gen. Georges André Hugonot, Medical Corps, French army, was cited July 21 by the commanding general of the Fifth Army, U. S. He was serving as corps surgeon of the French Expeditionary Corps on the Italian front.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Edgar Erskine Hume

Brig. Gen. Edgar Erskine Hume was recently awarded the Oak Leaf Cluster to the Distinguished Service Medal in recognition of service as chief of the Allied Military Government Section, Fifth Army, in Italy. The citation accompanying the award read:

"From Oct. 1, 1943 to Dec. 15, 1943, as chief of the Allied Military Government Section, Fifth Army, he successfully carried out one of the most extensive military government tasks ever accomplished by the United States, being charged with the government of Campania, a region of 6,000,000 inhabitants including Naples, one of Italy's largest cities. He made detailed plans for the administration of Naples, which, under his orders, were put into immediate execution when the city was taken on Oct. 1, 1943.

"Despite enormous handicaps in Naples, where the Germans had destroyed the water supply, electric power sources, drains and other public utilities, had mined buildings, despoiled hospitals, dispersed the police and in general paralyzed the civil administration, he was able by his unusual ability and devotion to duty to restore order forthwith and within a few weeks to return the city's functions almost to normal. A threatened epidemic of typhoid was averted by his wise preventive measures. Our victory was thus hastened, as the army commander was free to perform purely military functions without the added burden of civil government.

"The respect in which this officer was held by the Italians, his intimate knowledge of the country, its people and language, and his rare administrative skill and leadership made him unique in his efficient handling of an extremely difficult and politically delicate task."

General Hume was awarded the Distinguished Service Medal for his outstanding service as a medical officer during World War I as commissioner of the American Red Cross after the war in Serbia. He holds many decorations from foreign governments and numerous academic degrees from American and foreign institutions of learning.

General Hume graduated from Johns Hopkins University School of Medicine, Baltimore, in 1913 and was commissioned as a first lieutenant in the Medical Corps, Regular Army, Jan. 14, 1917.

Colonel Russell J. Caton

Col. Russell J. Caton, formerly of Bucyrus, Ohio, has received the Bronze Star for meritorious service at Guadalcanal, Solomon Islands, from May 13, 1943 to April 26, 1944. The citation reads "As island surgeon, Colonel Caton supervised and controlled medical service for thousands of troops at that base. In the supervision and coordination of twenty dispensaries and eleven hospitals he displayed unusual organizational ability, professional knowledge and leadership. He was directly responsible for the supply, storage and transport of medical equipment and supplies for operations on Guadalcanal and throughout the entire forward area. Under the expert guidance and force of purpose of Colonel Caton, the base medical service was developed to a widely extensive and efficient structure capable of meeting every exigency created by tropical climate and combat conditions. His careful planning and unerring sound judgment exemplify the highest tradition of the medical corps." Dr. Caton graduated from Ohio State University College of Medicine, Columbus, in 1913 and entered the service Feb. 1, 1941.

Colonel Frank B. Wakeman

The Legion of Merit was awarded posthumously to Col. Frank B. Wakeman, formerly of Indianapolis, for his meritorious work in connection with the training program of the Army Medical Department. The citation accompanying the award reads "For exceptionally meritorious conduct in the performance of outstanding services from July 1940 to March 1944. Colonel Wakeman, with rare foresight, initiative and organizing ability, laid the groundwork for the necessary expansion in all phases of Medical Department training, placing in operation replace-

ment training centers, service schools for officers, Medical Department enlisted technicians schools and an officer candidate school long before the entry of the United States into the war. As a result of his insight into medical requirements and the execution of plans, the Medical Department was able to expand greatly its training activities following Dec. 7, 1941 and also, because of the training already given, to render an efficient medical service to the Army during the very rapid expansion that followed the declaration of war. Colonel Wakeman's unusual foresight, aggressive execution of approved plans and selfless devotion to the best interests of the Army and the Medical Department are in the highest traditions of the service." Dr. Wakeman graduated from the Indiana University School of Medicine, Indianapolis, in 1926. The Association of Military Surgeons awarded him the Henry Wellcome Prize in 1938 for his thesis on an immunizing antigen of the typhoid bacillus.

Colonel John A. Rogers

Col. John A. Rogers, Army Medical Department, formerly on duty in Washington, D. C., as executive officer of the Office of the Surgeon General, has been awarded the Legion of Merit for services in the European theater. The citation stated that the award was given for "exceptionally meritorious conduct in the performance of outstanding services from Oct. 20, 1943 May 31, 1944." Dr. Rogers graduated from Tufts College Medical School, Boston, in 1914. He was formerly a member of the New Hampshire National Guard and entered the Medical Corps of the Regular Army in 1933, serving at posts in this country and in Hawaii.

Captain William I. Hunt

Posthumous award of the Silver Star Medal was recently made to Capt. William I. Hunt, formerly of Greenville, Miss., for gallantry in action. The citation accompanying the award read "Desiring to be where he was needed most, Captain Hunt accompanied a small reconnaissance patrol into Japanese territory. The patrol ran into an enemy ambush, which opened fire at a 30 yard range. During the action the lead scout was killed and three other men were wounded. Captain Hunt, disregarding his personal safety, courageously went forward under exposure to the heavy hostile fire toward the casualties and in doing so was mortally wounded. Although such bravery was neither ordered nor expected, this officer readily sacrificed his life in an attempt to help his wounded comrades." The organization to which Dr. Hunt belonged, the American Division, was the first army division to participate in offensive action in this war. Named for American forces in New Caledonia, where it was activated, it fought at Guadalcanal and is the only division officially with a name instead of a number. Dr. Hunt graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1942 and entered the service June 30, 1943.

Captain Ralph S. Phelan

The Silver Star award was recently given to Capt. Ralph S. Phelan, formerly of Waurika, Okla. The citation accompanying the award read "On Nov. 22, 1943, in the Mediterranean theater, he was battalion surgeon of an infantry battalion which was occupying a defensive position on a mountain top. Enemy artillery caused many casualties, and the rugged terrain made evacuation almost impossible. He went up the side of the mountain and administered first aid to the wounded in the battle area. His action under fire was credited with saving many lives." Dr. Phelan graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1939 and entered the service July 1, 1941.

Captain Andrew J. Extejt

The Bronze Star Medal was recently awarded to Capt. Andrew J. Extejt, formerly of Toledo. Dr. Extejt was decorated for military operations against the enemy in Normandy June 7-10. He has been overseas for more than a year and also saw action in Africa, Sicily and Italy. Dr. Extejt graduated from St. Louis University School of Medicine in 1934 and entered the service Aug. 27, 1942.

NAVY

NAVY AWARDS AND COMMENDATIONS

Captain Lockhart D. Arbuckle

Capt. Lockhart D. Arbuckle, now senior medical officer at the Naval Training Center, Great Lakes, Illinois, has been awarded the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as division surgeon of a Marine division during the planning for and the operations against the Japanese on Bougainville, British Solomon Islands, from Sept. 10, 1943 to Jan. 4, 1944. During this period Captain Arbuckle rendered invaluable assistance to the commanding general in executing the operation under the most adverse conditions. When the preparations for the establishment of the beachhead were begun, owing to his highly efficient supervision of the medical facilities all troops entered the combat areas in excellent physical condition. As a result of his exceptional professional skill and constant attention to duty, medical services were administered to all the wounded, and despite the trying conditions arising from tropical climate, losses from sickness and battle wounds among the troops were held to a minimum. His superior knowledge and sound judgment contributed materially to the success of the campaign and were in keeping with the highest tradition of the United States Naval Service." Dr. Arbuckle graduated from the Medical College of Virginia, Richmond, in 1915 and has been in the service since May 28, 1917.

Lieutenant Commander Richard Monroe Forsythe

Posthumous award of the Navy Cross has been made to Lieut. Comdr. Richard Monroe Forsythe, formerly of Cleveland. The citation accompanying the award read "For extraordinary heroism while serving as regimental surgeon with the . . . First Marine Division, during action against enemy Japanese forces near Volupai Plantation, Willaumez Peninsula, New Britain, on March 6, 1944. When our forces suffered severe casualties while landing on the strongly fortified beach, Lieutenant Commander Forsythe immediately went to the assistance of the wounded and, undeterred by devastating hostile mortar fire, untiringly administered medical aid to the injured and assisted in moving them out of range of Japanese guns. Courageously remaining in the exposed area despite multiple wounds from a bursting enemy mortar shell, he continued ministering to the injured until severe pain finally forced him to cease his valiant efforts. Although fully aware that postponed surgical attention would gravely impair his chance of recovery, Lieutenant Commander Forsythe steadfastly refused medical assistance while there were other casualties in need of care and later succumbed as a result of wounds received in this action. His outstanding professional skill, his great personal valor and heroic devotion to duty were an inspiration to his associates and reflect the highest credit on the United States Naval Service. He gallantly gave his life for his country." Dr. Forsythe graduated from Western Reserve University School of Medicine, Cleveland, in 1937 and entered the service May 31, 1940.

MISCELLANEOUS

MORE THAN 400 FROM POST-GRADUATE
HOSPITAL NOW SERVING WITH
ARMED FORCES

More than 400 physicians, nurses and others connected with the Post-Graduate Hospital, New York City, are now serving with the armed forces. The number of physicians attached to the Army, Navy and Marines in various battle fronts is one of the largest from any hospital in the country. Doctors from the attending staff of the hospital number 296, while there are 47 from the intern and resident units. In addition to these there are 47 nurses, who, like the doctors, are volunteers. One member of the hospital staff has been killed in action, and those drafted from the nonvolunteer group have reached a total of 36.

The Post-Graduate veterans now in uniform will often be reminded of their home service by the fact that they will use some of the flying ambulances for the transfer of their patients. Owing to the success of the "E bond" campaign conducted at the hospital, three of these great air ambulances will carry the name of the Post-Graduate Medical School and Hospital.

The medical school is engaged in arrangements for classes and courses for military doctors returning to their civilian practices, scores of whom have asked for this training.

RESTRICTIONS ON USE OF
AGAR REMOVED

The War Production Board recently announced that stockpiles of agar, formerly dependent on supplies received exclusively from Japan, have now been improved to such an extent by newly developed domestic production and by imports from Mexico that restrictions on the use of agar have been removed, by revocation of Order M-96. Agar, a jelly-like substance extracted from certain types of seaweed found on both the Atlantic and Pacific coasts, is principally used in making bacteriologic cultures, but only the seaweed found on the West Coast yields the type of agar that can be used for the production of these cultures. Agar is also used in the preparation of medicinals, pharmaceuticals and food, and in the drawing of tungsten wire and the manufacture of dental impression compounds.

Domestic production of agar was accomplished as a result of close cooperation between industry and the Chemicals Bureau of the War Production Board. The largest agar plants, the American Agar and Chemical Company, is situated in Los Angeles. Smaller agar production units have been established in Massachusetts, the Carolinas and Florida.

To insure fulfillment of any emergency needs for agar, a stockpile is being reserved by the Defense Supplies Corporation, a subsidiary of the Reconstruction Finance Corporation.

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL September 2, page 37)

CALIFORNIA

Santa Clara County Hospital, San Jose. Capacity, 470; admissions, 4,435. Dr. Henry E. Dahleer, Superintendent (resident—tuberculosis).

KENTUCKY

Louisville General Hospital, Louisville. Capacity, 587; admissions, 9,805. Dr. John W. Moore, Medical Director (1 intern, 1 assistant resident—medicine, October 1).

MICHIGAN

Leila Y. Post Montgomery Hospital, Battle Creek. Capacity, 165; admissions, 6,301. Sister Mary Constance, Administrator (intern).

NEW YORK

Israel Zion Hospital, Brooklyn. Capacity, 380; admissions 10,532. Dr. J. Praeger, Executive Director (interns, October 1944, January 1945).

RHODE ISLAND

Buller Hospital, Providence. Capacity, 175; admissions, 178. Dr. Arthur H. Ruggles, Superintendent (residents—psychiatry).

TEXAS

All Saints Episcopal Hospital, Fort Worth. Capacity, 100; admissions, 3,997. Miss Eva M. Wallace, R.N., Superintendent (resident—mixed).

WISCONSIN

Methodist Hospital, Madison. Capacity, 127; admissions, 3,911. Miss Carolyn M. Fenby, R.N., Superintendent (interns).

URGENT SPECIAL MICROSCOPIC TESTS BEFORE TREATING GONORRHEA WITH PENICILLIN

Dr. C. J. Van Slyke of the Public Health Service Venereal Disease Research Laboratory, Staten Island, N. Y., and Dr. S. Steinberg of the U. S. Marine Hospital, New York City, recently reported the possibility of overlooking syphilis symptoms in gonorrhea patients treated with penicillin in patients who have both diseases. This can be avoided, however, if special microscopic tests are made before penicillin is used, and if blood tests are made after penicillin treatment has been completed. The masking effect of penicillin on syphilis symptoms is due to the fact that the relatively small amounts of penicillin required to cure gonorrhea are sufficient to cause disappearance of the spirochete germs of syphilis from syphilis lesions, although not sufficient actually to cure syphilis. When serum from the lesions is examined under a special microscope after penicillin has been used, the spirochetes will not be seen, and the examining doctor may be misled to conclude that the patient was not infected with syphilis. Making the microscope examination before treatment with penicillin prevents this possible error. A blood test for syphilis some time after the treatment of gonorrhea has been completed is advisable, because blood tests do not always reveal very new syphilis infections immediately after they have been acquired.

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America (420 Lexington Avenue, New York City) recently donated a shipment of medical supplies, including five cases of fracture pillows, crutches, stretchers, wheel chairs and a fracture cradle for use of wounded soldiers, to the Halloran General Hospital, Staten Island, N. Y. The Medical and Surgical Relief Committee of America was organized four years ago and is conducted by a nationwide group of physicians, surgeons and dentists. The committee is a philanthropic organization dedicated to medical, surgical and dental aid for the armed and civilian forces of the United Nations. To date the committee has shipped and delivered safely in America more than \$640,000 of supplies.

PRINTED FORMS FOR CADET NURSES WHEN TRAVELING

Some members of the U. S. Cadet Nurse Corps have encountered transportation difficulties through being confused with members of the armed forces. In one instance a cadet nurse was unable to purchase a train ticket because a passenger agent, thinking her a member of some governmental service, requested to see furlough papers, which of course she did not have. This occasioned an expensive delay in her trip. In order to avoid this possible confusion the U. S. Public Health Service is printing forms which will be sent in the near future to directors of schools of nursing which (when signed) are to be given to cadet nurses who are traveling in uniform. This will clarify the situation for any agent who, in line of duty, might question their right to travel. Additional forms will be sent to the directors of schools of nursing on request.

COMMITTEE ON MEDICAL RESEARCH BEGINS PUBLICATION

The Committee on Medical Research of the Office of Scientific Research and Development began publication recently of a weekly journal entitled *Summary of Reports Received by the Committee on Medical Research*. Circulation of the publication is restricted to selected Medical Corps men in the United States, Canada and Great Britain. The journal is being edited and published by the records section of the committee, the work of which is directed by Dr. Kenneth B. Turner, who is on leave of absence from Columbia University College of Physicians and Surgeons.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

At Camp Ellis, Illinois: Conditions Affecting Glucose Metabolism, Drs. Arthur R. Colwell and George W. Seupham, September 20.

At Camp Grant, Illinois: Recent Advances in the Treatment of Syphilis, Drs. Robert M. Craig and George X. Schwemlein, September 20.

At Chanute Field, Rantoul, Ill.: Chemotherapy—Present Status, Drs. W. Barry Wood Jr. and Italo F. Volini, September 20.

HEALTH NEWS FROM EUROPE

According to DNB of May 13, 1944 (Germany) hospitals have time and again been the target of enemy terror bombers. Far sighted vision revealed many years ago the need for sick persons to be lodged outside towns, in a place where they would be safe from air attacks. Prof. Dr. Brandt, the führer's general commissioner for the medical and health services, was entrusted by the führer with the task of devising and applying the necessary measures. Under the technical direction of Dr. Poschmann, delegate of the general commissioner for hospital emergency installations and of Ministerial-Direktor Schönleben of the building office in the Speer ministry, emergency hospitals were built in several stages at many places all over the reich. Although they are in the nature of emergency hospitals they combine all the qualities of an up to date hospital building with the added advantage of being close to nature, which is particularly beneficial to the sick and also affords protection from air attacks.

Reich Minister Speer gave press representatives an opportunity to inspect such a hospital which is under construction in the neighborhood of the reich capital. The friendly and airy rooms with their white ceilings make one oblivious of the fact that they are really huts. In planning the site the "pavilion" system was abandoned and the six wards form a close structure; they are connected by a 250 meter brick corridor, which makes it possible to move within the hospital, regardless of temperature and weather, exactly as in the several floor building of the town hospital. Each ward consists of several fair sized sickrooms with 6 to 8 beds each, while the smaller sickrooms, wash rooms and bath rooms and a cory common room are situated on the other side of the passage. In each ward there is room for the offices of the doctors and sisters and a kitchenette on the other side of the main connecting corridor. A modern central kitchen for the whole hospital is situated at one end of this corridor, while at the other end is the ward for infectious diseases, which is completely isolated from the other wards and in its design is probably the most up to date of its kind in Europe. Situated between the wards exactly in the center of the whole site is the reception and treatment hut, which also houses the x-ray units and the laboratory and contains the consulting rooms of the dentist, the ophthalmologist and other specialists.

Many such hospitals were completed in the neighborhood of many air raid danger towns during the last four months; despite wartime difficulties it was possible to complete the buildings in the short space of six to eight months. Each hospital has 500 beds and in an emergency will hold as many as 800. Germany disposes already of 15,000 such beds, while space is being provided for thousands more. New methods are also being employed in the administration of these emergency hospitals. They are under the direction of General Commissioner Dr. Brandt, to whom the senior house surgeon is responsible in all matters. This procedure eliminates red tape, particularly in questions of hospital supplies and also in the admission of patients; they are treated there regardless of who is to pay.

These hospitals will naturally be used in the first place to house serious cases and others which it will take some time to cure, while the hospitals in the towns will continue to be available for day to day cases.

The Netherlands Information Bureau states that a group of prominent physicians recruited from American medical schools and hospitals will leave for the Netherlands after that country's liberation to give a series of four week postgraduate refresher courses in Dutch universities. This plan was announced by Dr. Herbert Loeb of Cambridge, Mass., former president of the Netherlands Dental Association at Amsterdam, who was instrumental in arranging for a similar postwar movement to bring dental care to the Netherlands. Nine medical specialists will make the transatlantic voyage to give the refresher courses, which cover eight specialties and have been prepared in both the English and the Dutch languages. The Netherlands government will finance the traveling and other personal expenses of the American professors, who will, however, receive no extra or special compensation for their work in the Netherlands. Because of German looting of Dutch medical schools and hospital equipment, the physicians will take with them all material and instruments needed for laboratory and demonstration purposes.

The idea of these refresher courses originated with Dr. Herman deJong of Duke University, formerly of the University of Amsterdam, where he specialized in neurology and psychiatry for the Dutch branch of the Rockefeller Foundation. He discussed his plan with Dr. Gerrit Bolkestein, Netherlands minister of education, when the latter toured a number of American universities last May, who approved the plan. In addition to Dr. deJong, the expedition will include Dr. Frederick M. Hanes, clinical medicine; Dr. Keith S. Grimson, surgery; Dr. David T. Smith, bacteriology and infectious diseases; Dr. Edwin C. Hamblen, obstetrics, gynecology and hormonology, all of whom are from Duke University School of Medicine, Durham, N. C.; Dr. Wilburt Davison, dean of Duke University School of Medicine, pediatrics. Dr. Isidore Snapper, director of the Department of Graduate Medical Education at Mount Sinai Hospital, New York, will also cover clinical medicine. Dr. Snapper left the University of Amsterdam in 1937 to go to the Rockefeller Foundation at Peiping, China. He was captured by the Japanese and later sent to America as an exchange prisoner. Other members are Dr. C. J. Van Slyke of the Rockefeller Institute, New York, biochemistry, and Dr. Eli K. Marshall Jr., Johns Hopkins University, physiology and pharmacology.

According to *Le journal* of May 18, diets for sick people are granted only on production of a medical certificate drawn up on a printed and numbered form delivered monthly for three periods of ten days. The control is severer as regards No. 1 and feeding up diets, which are granted with the greatest parsimony for only five, seven and sometimes ten days. Each doctor now receives, through the medical council, five printed forms per thousand inhabitants of his district. Thus a skin or eye specialist is entitled to prescribe the same number of diets as a child specialist, whose patients need most feeding up. The results of this measure were that in one Lyons arrondissement the number of persons entitled to diet No. 2 fell within a month in the proportion of four to one. Under diet No. 2 the meat, cheese and wine rations can be replaced by 0.25 liter of milk daily and 750 Gm. of spaghetti, 750 Gm. of sugar and 6 Kg. of potatoes monthly. Those entitled to this diet are generally old persons unable to eat the present meat, and for whom doctor's fees are often an extravagant expenditure which they cannot afford to repeat monthly, preferring to give up the diet. It is incomprehensible that certain patients cannot be treated because the doctor has used his five diet vouchers. Thus the district doctor is often compelled to deprive of their diet those who need it most.

According to *Der Bund*, Berne, of June 28 it is not known whether the decision of the French medical council whereby no doctor may leave the Paris region without the permission of the council is connected with the communiqué extending the compulsory labor service to doctors, or whether it is merely intended to prevent the regrettable situation which arose in the summer

of 1940 owing to the mass flight of doctors. The council's circular adds information about the difficulties facing the medical profession owing to the restrictions on electricity and gas in the Paris district. X-rays can no longer be used either in hospitals or in private consulting rooms. It is almost impossible to sterilize instruments. The modest supplementary distribution of methylated spirit is inadequate.

DNB of May 15, 1944 (Germany) states that the penal regulations on professional abortion have been tightened up by the order for the protection of marriage, family and motherhood. The penal code now provides for the death sentence in cases in which the vitality of the German people has been impaired by continuous abortion. The special court at Frankfurt on the Oder applied this new provision of the law against Heinrich Schulz of Balkow, Kreis West-Sternberg. Schulz had carried out altogether nine abortions and thus committed a particularly grave sin against the future of his people. He was sentenced to death as a dangerous habitual criminal for professional abortion. The sentence has already been carried out.

The DAF announced that five hundred theater performances and lectures were held for Dutch workers in Germany in April, according to the German European Service of May 24, 1944. Medical care for foreign workers in Germany has been further improved. Three hospitals in central Germany have been opened exclusively for their use equipped with the most modern installations, special departments for infectious diseases and clinics for women. Doctors and nursing staff are recruited from Germany and many European countries.

SNP (Norway) reports, according to *Aftontidningen*, Stockholm, of June 21 that a number of young Oslo girls were recently conscripted for "national labor service" in German military hospitals in Oslo and the surrounding districts. The Norwegian home front boycott of conscription included such conscriptions, and if the German authorities continue to summon Norwegian girls, then the girls may find themselves in the same situation as men conscripts.

The Chambery medical board, considering the prohibition of night automobile traffic, the substantial fuel reduction and telephone restrictions, earnestly asks patients to abstain from calling doctors at night, since it is virtually impossible to travel after 10 p. m., according to *Le Nouvelliste de Lyon* of June 17. The most distant patients can be visited only in daylight by taxi.

Transocean (for the Far East) of May 12, 1944 (Germany) states that the first bomb proof dispensary has been opened in a Ruhr town. Built into a steep slope, it is 13 meters long but only 3 meters wide and 2.8 meters high. Ten cupboards contain 5,000 types of drugs and medical supplies, sufficient to meet four weeks' requirements.

Radio Paris of May 22 reports from Brussels that during the night of May 19 a large quantity of anesthetic drugs was stolen by unknown persons from a depot of pharmaceutical products, including a large quantity of crude morphine destined for hospitals and clinics. The stolen goods are valued at about 2 million francs.

The minister of the interior, according to *Slovo* of March 3, 1944, has signed an order published in the Official Gazette of March 24 stating that the fees paid in private hospitals and sanatoriums in the country are increased by 100 per cent over what they were in 1936.

The Mulhauser *Tagblatt* for April 20 (Alsace) states that by a decree dated March 4 (published in the *Verordnungsblatt des Chefs der Zivilverwaltung im Elsass* of April 4) the law introduced in the reich on July 14, 1933 for the prevention of hereditary disease in the rising generation is now valid in Alsace.

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

Sept. 4, 1944.

Hearings on Blindness and Infantile Paralysis

Sixty per cent of the cases of blindness in this country are unnecessary and could be prevented, Dr. Harry S. Gradle, professor of ophthalmology at the University of Illinois College of Medicine and vice president of the Illinois Society for the Prevention of Blindness, testified here this past week before the Kelley Labor Committee Subcommittee to investigate aid to the physically handicapped. He spoke as a representative of the American Medical Association. Dr. Gradle deplored the fact that there are not sufficient agencies where a newly blinded person can become accustomed to his affliction and get training in new uses of his senses and capabilities. He suggested centers such as those now operated by the Army and Navy for reconditioning men blinded in war. Prevention of blindness, he contended, "is of even greater importance than care for the blind."

Dr. Gradle recommended that state public assistance commissions be assisted in the physical rehabilitation of the blind. "There are enlisted," he said, "6,000 ophthalmologists in the United States, of whom a little over 2,000 have been certified as being ophthalmologists and 2,000 who are doing capable work without certification. The other 2,000 comprising the 6,000 are mostly general practitioners who are doing a small amount of ophthalmology on the side but who are not capable of doing necessary rehabilitation work." He explained later that "the number we have is sufficient for the physical rehabilitation of the blind. The 6,000 in existence are not enough to cover the needs of the general population of the United States, apart from rehabilitation."

Dr. Gradle was followed as a witness by Dr. Allan C. Wood, director of the Department of Ophthalmology in Johns Hopkins University School of Medicine and director of the Wilmer Ophthalmological Institute, who expressed the opinion that the Sanders 1934 estimate of 150 blind persons per hundred thousand, or from 215,000 to 240,000 blind in the United States, was most accurate of all estimates and "a fair guess." He quoted National Health Survey figures on the incidence of blindness in the 100,000 of population, as follows: "You will find that 11 per hundred thousand of the population are blind under 15, and that figure steadily goes up, so that for the ages between 45 and 54 you find that 90 per hundred thousand are blind, and when you get to 75 to 84 you find that approximately 1,000 per hundred thousand are blind, and when you get to 85 plus, prac-

tically 3,000 per hundred thousand of the population are blind. The answer to that is that the people are moving in their advancing age to the time when the various diseases take their toll of blindness."

These two witnesses were among a score or more heard by Representative Augustine B. Kelley (Democrat, Pennsylvania) in the study on blindness. During the present week it is proposed to hear experts testify regarding the prevalence of infantile paralysis to determine if adequate facilities are available for its treatment. The purpose of the hearings, according to Representative Kelley, is to "learn the causes of the handicaps and the means to cure or alleviate them, to provide the afflicted with educational opportunities, training and restoration to gainful occupations, and to assist those who cannot be employed."

Postwar Hospitalization Under Study

Favorable indications for the bill providing federal aid to build a cooperative hospital center in Washington, to be operated on a self-sustaining and nonprofit basis, have stirred interest here generally in United States postwar hospitalization needs. Senator Millard Tydings (Democrat, Maryland), one of the chief sponsors of the bill, has expressed the conviction that Congress would approve the plan, in which participating hospitals here would pool their resources to carry the full load of maintenance costs. He emphasized that Congress was not expected to contribute anything toward the annual expenses.

The pending plan calls for construction of a 1,500 bed hospital center in which any of Washington's private hospitals could join as participating or associate members. The cost is estimated at between \$6,000,000 and \$7,500,000 exclusive of land. To date only Garfield and Emergency hospitals have decided to join the center as full participating members.

Health authorities here have shown interest in what has been done by the Cleveland Hospital Service Association to help people meet the cost of illness without leaning on the government for funds or control. Eight hundred thousand people in the greater Cleveland area are entitled to benefits, with 55 per cent of all the residents of the community enrolled in the service and currently adding 100,000 additional subscribers annually. Each subscriber to the association makes a small monthly payment, which insures him or a member of his family of proper hospital care when necessary. In its ten years of existence the association has provided such care for 300,000 patients. The Cleveland Hospital Service Association, one of the pioneer organizations of its kind, provides hospitalization only and does not include services of the physician or surgeon. It is one of seventy-eight such associations operating in the United States, details of operations differing in various communities.

MEDICAL ECONOMIC ABSTRACTS

CALIFORNIA PHYSICIANS' SERVICE

A REPORT BY THE BUREAU OF MEDICAL ECONOMICS

The California Physicians' Service has just issued its fifth annual report, so comprehensive as to various phases of the operation of the plan as to form an excellent guide to other state and local medical associations considering the establishment of a prepayment plan. As the first statewide plan, California has been forced to experiment in many directions. It has issued several types of contracts. It still retains a number of these as suited to special conditions. Its largest enrollment is now under the surgical service contract, in which membership dues per month are \$0.60 for male employees, \$0.90 for female employees, \$1.50 for an additional dependent and \$2.25 for two dependents. Participation is limited to those with incomes under \$3,000 a year, to whom all contracted services are granted.

Employed beneficiary members under the surgical contract may obtain a "two visit deductible medical rider." With a few

exceptions this covers a complete medical service for the payment of 75 cents a month in addition to the regular surgical contract rate. To meet the demand for those with an income of more than \$3,000 an indemnity surgical reimbursement contract is issued under which patients make their own arrangements with physicians and receive reimbursement under the regular schedule of the surgical contract.

In northern California territories California Physicians' Service has found it necessary to cover hospitalization as well as surgical services. The hospital rider rates per month are 75 cents for the employed man, 80 cents for the employed woman and \$1.80 and \$2.40 for one and two or more dependents respectively.

Service is also furnished for farm families with an income of less than \$2,000 a year. This program, conducted in cooperation with the Farm Security Administration, provides for medical, surgical and hospital care to all members of the family alike. A fee of \$1.50 must be paid by the patient for the first home visit, and there are some other minor limitations. The rates annually are \$30 for single persons, \$48 for a family of two and \$60 for a family of three or more.

As a special war emergency undertaking, the California Physicians' Service entered into contracts to provide medical, surgical and hospital care to residents of projects under the jurisdiction of local housing authorities. Monthly rates were \$2.50 for single persons, \$4 for a family of two and \$5 for larger families.

The experience with the Rural and Housing Project contracts has gained a necessary knowledge of methods of cooperation with government bodies as well as of the variations in service required under these different conditions. At present California Physicians' Service is paying 90 per cent of what might be called the normal unit value. At one time in 1940 the amount paid per unit was \$1.10 and in February 1944 it was \$2.25. In the meantime the "unit state fund" has been increased to \$70,000. It is hoped that this backlog will avoid such violent fluctuations

in the future. While fairly good relations have been established with such diverse bodies as labor organizations, membership served, hospitals and government agencies, the relations with the medical profession, etc., still remains "the most urgent problem of C. P. S. . . . Without an active and positive support from its professional members, C. P. S. cannot grow, and if it cannot grow it will never reach its true value to the medical profession. C. P. S. is an agency composed of its professional members. It must, regardless of the personal desires of individuals, function as the bulk of its members wish. It cannot perform its purposes in any other manner. . . .

Many of the problems of acquisition are directly related to the lack of professional member support and the lack of labor and employer support.

DISCUSSIONS ON POSTWAR SECURITY

National Health Plan Advocated by Dr. Parran

The United Press reports that a postwar national health program, supported by insurance and taxation, was proposed by Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, in a Labor Day address at the University of California medical center, San Francisco. He suggested that the program should not be "entirely socialized or an entirely private undertaking but a combination of both."

Health Plan Offered to Workers in East

According to the United Press, incorporation papers for a health insurance plan covering all persons living or working in New York and earning not more than \$5,000 annually have been filed with the state board of social welfare and the superintendent of insurance. The plan, providing medical and surgical care, is expected to be ready for operation by January 1, with most of the city's 190,000 employees and many union members enrolled, Mayor F. H. LaGuardia announced. Incorporators include Henry J. Kaiser, West Coast shipbuilder; former Governor Alfred E. Smith, and Beardsley Ruml, chairman of the board of the Federal Reserve Bank; Gerard Swope, chairman of the board of the General Electric Company, Sidney

Hillman, president of the Amalgamated Clothing Workers Union; Wendell Willkie, and the borough presidents.

Eric Johnston Speaks

According to the *Chicago Tribune*, high praise for America's private security system of insurance as compared with any "incentive stifling bureaucracy" contemplated in a postwar super-federal social security system was given by Eric Johnston, president of the Chamber of Commerce of the United States, in an article which will appear in the forthcoming issue of the *Casualty and Surety Journal*. "The private security system of insurance is as American as apple pie," Johnston wrote, "for it was conceived and developed in the adventurous American spirit of individual initiative and enterprise. No sprawling, incentive stifling bureaucracy is this dynamic system, but a nationwide industry, composed of 524,000 self-reliant employees and producers earning their own way in the world, keeping in step with the pulsating tempo of progress." Johnston said that, through private enterprise, a supersocial security system is already here and questioned "the need of elaborate blueprints for a superfederal social security system."

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—The Kelley subcommittee of the House Committee on Labor has scheduled hearings for September 12, 13 and 14, at which time testimony will be received relating to the aid given to the hard of hearing and the deaf. H. R. 1506 has passed the House and Senate, and Senate amendments have been agreed to by the House, proposing to amend further the Pay Readjustment Act of 1942. This bill, among other things, will permit the counting of services in the Medical Reserve Corps for pay purposes. H. R. 5257 has been reported to the House, a bill to provide for health programs for government employees, with an amendment exempting the Tennessee Valley Authority from the scope of the bill. Health services now provided by any governmental agency will continue until June 30, 1945, at which time the Civil Service Commission in consultation with the United States Public Health Service will supervise such health activities.

Bills Introduced.—S. J. Res. 147, introduced by Senator Langer, North Dakota, would authorize an appropriation of \$10,000,000 for the investigation and study of the origin, causes and means of control of infantile paralysis. This resolution proposes to create an Infantile Paralysis Control Board to be composed of the Surgeon General of the Public Health Service as chairman and one outstanding member of the medical profession in each state and in the District of Columbia to be appointed by the Surgeon General. The Surgeon General will also be authorized to "appoint Sister Kenny, the famed Australian nurse, as a member of the board." H. J. Res 305, introduced by Representative Priest, Tennessee, would authorize the Surgeon General of the United States Public Health Service to dispose of certain reserves of liquid, frozen or dry blood plasma or serum albumin to federal, state or local public health authori-

ties or to federal or other nonprofit hospitals. This plasma or albumin is being held in reserve for casualties resulting from enemy action and disposition is to be made of it when the Surgeon General determines that it is no longer needed for the purpose for which it is held in reserve. H. R. 5249, introduced by Representative Rankin, Mississippi, contemplates an amendment to title II of the G. I. Bill of Rights, relating to the education and training of returning veterans, to provide that if any publicly supported institution or private institution exempt from tax under section 101(6) of the Internal Revenue Code has no established tuition fee, or if the established tuition fee is less than the actual cost to such institution of furnishing the education and training, the Administrator of Veterans' Affairs will be authorized to provide for the payment to such institution of the actual cost of furnishing education or training to a veteran, but not to exceed \$500 for an ordinary school year.

DISTRICT OF COLUMBIA

Bills Introduced.—S. 2074, introduced by Senator Tydings, Maryland, for himself and Senator Bilbo, Mississippi, and H. R. 5183, introduced by Representative Harless of Arizona, propose to provide for the establishment of a modern, adequate and efficient hospital center in the District of Columbia. A subcommittee of the Senate Committee on the District of Columbia has conducted hearings on S. 2074. It is understood that the Medical Society of the District of Columbia has approved the bill in principle on condition that all nonprofit voluntary hospitals affording service to indigents and near indigents in the District be given equal opportunity to participate in the program and on condition that they be assured equal representation in the corporate body created by the bill, namely the Washington Hospital Corporation.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Symposium on Penicillin.—The San Francisco County Medical Society devoted its August 8 meeting to a symposium on penicillin at which the following participated:

- Dr. Lowell A. Rantz, The Background of Penicillin Therapy.
- Dr. Arthur L. Bloomfield, Special Problems in the Clinical Uses of Penicillin.
- Drs. Horace J. McCorkle and Henry L. Silvani, Uses of Penicillin in Surgical Infections.
- Comdr. Clark M. Johnson (MC), Uses of Penicillin in Infections of the Genitourinary Tract.

Course on Occupational Dermatoses.—Dr. Louis Schwartz, medical director of the dermatoses section of the U. S. Public Health Service, will conduct a course on occupational dermatoses at the Los Angeles County Medical Association, Los Angeles, September 18-23, under the auspices of the University of Southern California School of Medicine and the College of Medical Evangelists, the Los Angeles Chamber of Commerce and the Los Angeles County Medical Association.

Physician Wanted.—The Los Angeles County Civil Service Commission announces that a chief physician (tuberculosis) is wanted to administer the tuberculosis service of the Los Angeles County Hospital or to assist in directing medical care and treatment of patients at Olive View Sanatorium and to act as tuberculosis consultant. Physicians under 55 years of age who have an M.D. degree and three years' recent experience or training in the specialty of tuberculosis are urged to apply for this position, which carries a salary of from \$417 to \$489 a month. Full information and applications may be obtained from the office of the commission, Room 102 Hall of Records, Los Angeles 12. Applications must be filed on or before September 16.

DELAWARE

Committee for Postwar Planning.—The state medical society has appointed a committee of nine to be known as the Committee of Postwar Planning of the Medical Society of Delaware, composed of the following members: Drs. Richard C. Beebe, Lewes; Joseph B. Waples Jr., Georgetown; John Roscoe Elliott, Laurel, representing Sussex County; Joseph S. McDaniel, Dover; William Marshall Jr., Milford, representing Kent County; William O. LaMotte, William Edwin Bird, Frederick A. Hemsath, secretary, all of Birmingham, and Mesrop A. Tarunian, Farnhurst, chairman, representing New Castle County. A survey of medical and hospital services of all types will be carried out in sections of the state to aid the committee in studying adequate medical services of various specialties for every community of the state, various hospital facilities, medical service to industry, large and small, adequate medical service of all types for public schools, the need for closer relationship between all existing state, municipal and private postwar planning organization and hospitals to enlist the full cooperation of all physicians and hospitals for rehabilitation of veterans. The society, which believes that as a scientific organization it cannot achieve the desirable level of success unless it becomes an integral part of the economic and social structure of the country, will cooperate with the state legislature, state administration, various boards of education, various industrial and agricultural organizations, chambers of commerce, bar association, state and municipal and private, social, civic and religious agencies, all labor unions promulgating the definite policy that sound health is the business of every citizen and the prerogative of progressive people, and that this can be achieved through the help and cooperation of organized medicine.

ILLINOIS

Stuart Wood Memorial Fund.—Plans are under way to establish a memorial fund in honor of the late Dr. Wilbur Stuart Wood, Decatur. The memorial will take the form of a fund to be used to purchase orthopedic equipment in the Decatur and Macon County Hospital, where Dr. Wood had been active for many years. Dr. Wood died August 7.

Chicago

Rongetti Sentenced to County Jail.—Amante Rongetti, whose license to practice medicine was revoked in 1932 when he was sent to the state prison at Joliet following his conviction of manslaughter, was sentenced August 30 to three months in the county jail for practicing medicine without a license and fined \$500. Newspapers reported that the sentence was imposed by Judge Russell W. Keeney of Du Page County sitting in county court. Rongetti is also reported to have served a term in the federal penitentiary at Leavenworth for violating the federal narcotic act. At the trial, June 14, Rongetti was found guilty by a jury after an inspector for the state department of registration and education testified that he had prescribed distilled water for a "supposed kidney ailment." Ray E. Lane, Rongetti's attorney, said he would appeal.

Assembly on Nervous and Mental Diseases and War.—The Institute of Medicine of Chicago will hold its post-graduate assembly, November 1-2, at the Palmer House. The program will cover "Nervous and Mental Diseases and War" and will be devoted to phases of neurology, psychiatry and neurosurgery that are of particular importance to clinicians, specialists and lay workers. There will be a registration fee of \$5 for all except those in uniform. Among the speakers will be:

- Dr. Samuel W. Hamilton, Washington, D. C., Psychiatry Before World War II.
- Dr. Winfred Overholser, Washington, Civilian Mental Health in War-time.
- Dr. C. Charles Burlingame, Hartford, Conn., Present and Future Effects of War Neuroses.
- Dr. Bernard J. Alpers, Philadelphia, War and Nervous Disorders.
- Dr. Cobb Pilcher, Nashville, Tenn., Civilian Advances and Investigations in Neurosurgery During the War.
- Col. William C. Menninger, M. C., The Mentally Unfit: Detection, Elimination and Disposal.
- Lieut. Col. Roy R. Grinker, Psychiatric Disorders in Combat Crews Overseas and in Returnees.
- Dr. Edwin G. Zabriskie, New York, Nervous Disorders in the Armed Forces.
- Capt. Winchell M. Craig, M. C., Injuries to the Central Nervous System.
- Dr. Howard C. Naffziger, San Francisco, Injuries to the Peripheral Nervous System.
- Luther E. Woodward, Ph.D., New York, Social Readjustment of Returning Veterans.
- Lieut. Comdr. Howard P. Rome (MC), The War and Its Psychiatric Problems.
- Dr. David J. Margolis, Chicago, Compensation Laws and the Veterans Administration.
- Dr. Sidney I. Schwab, St. Louis, Residuals of Neuropsychiatric Disorders.
- Dr. Ernest Sachs, St. Louis, Residuals of Neurosurgical Disorders.

The program will include a series of panel discussions on war neuroses or battle fatigue? war injuries to the nervous system, does war modify the behavior of the civilian population? and who are the mentally unfit for military service? The first evening session will include a neuropsychiatric "information please" program with Dr. Foster Kennedy, New York, as moderator. On the second evening Dr. Edward A. Strecker, Philadelphia, will deliver the seventeenth annual Pasteur lecture of the institute on "War Psychiatry and Its Influence on Post-war Psychiatry and Civilization."

KANSAS

Jack Austin Dies.—Capt. Jack F. Austin, executive secretary of the Sedgwick County Medical Society from 1937 until 1942, when he went into military service, was killed recently while on maneuvers in South Carolina, according to the *Medical Bulletin* of the Sedgwick County Medical Society.

William Abramson Named Supervising Ophthalmologist.—Dr. William F. Abramson, Topeka, has been appointed state supervising ophthalmologist for the division of service for the blind of the Kansas State Board of Social Welfare, succeeding Dr. William W. Reed, Topeka. The appointment is effective for an eighteen month period.

MASSACHUSETTS

Advisory Committee for Endorsement of Heavy Cream.—In Massachusetts authority has been given to the district supervisor of the Office of Distribution to make a reasonable interpretation of the terms of amendment 2 to War Food Order number 13, emanating from the Office of Distribution of the War Food Administration, providing that medicinal prescriptions for heavy cream must be approved by the public health officer or the secretary of the county medical society of the area where a patient or hospital is situated. The *New England Journal of Medicine* reports that the endorsing function has, by this interpretation, been vested in an advisory committee composed of John H. Sullivan, district

supervisor, Office of Distribution, War Food Administration, chairman; Dr. Vlado A. Getting, Boston, state commissioner of health; Dr. G. Lynde Gately, Boston, city health commissioner; Dr. H. Quimby Gallupe, Boston, secretary, state board of registration in medicine; Dr. Nathaniel W. Faxon, medical director, Massachusetts General Hospital, Boston, and Drs. Francis Gorham Brigham, Brookline; Joseph Garland, Boston; Loring Grimes, Swampscott, and Franklin W. White, Boston, representing the Massachusetts Medical Society.

MICHIGAN

Seminar on Speech Rehabilitation.—The speech clinic of the University of Michigan, Ann Arbor, announces an intensive training course for veterans with speech and hearing disabilities. The course will begin November 6 and continue for six weeks. This program will be similar to one mentioned in *THE JOURNAL*, June 17, page 504.

Personal.—Melville Sahyun, Ph.D., has been named divisional vice president of Frederick Stearns and Company, Detroit, Division of Sterling Drug, Inc. Dr. Sahyun has been associated with Stearns since 1934, first as director of biochemical research and since 1943 as director of research. He developed the first amino acid preparation for parenteral administration in man and his book "An Outline of the Amino Acids and Proteins" will soon be published.

Fredrick Yonkman Joins Ciba Company.—Dr. Fredrick F. Yonkman has resigned as professor of pharmacology and therapeutics and chairman of the department at Wayne University College of Medicine, Detroit, to accept a position as chief pharmacologist in the research division of Ciba Pharmaceuticals, Inc., of Summit, N. J. Other changes in the pharmacology staff include the resignation of Dr. Harold F. Chase, assistant professor, to accept a similar position in the Western Reserve University School of Medicine, Cleveland, and Bradford N. Craver, Ph.D., as research associate to become instructor and director of pharmacologic research conducted under governmental contract at the University of Rochester, N. Y.

NEW JERSEY

Personal.—Dr. Jacob Cohen, formerly acting clinical director of Central Islip State Hospital, Central Islip, N. Y., has been appointed assistant director of the Newark State School, Newark. Since the death of Dr. August E. Witzel, May 15, Dr. Hiram G. Hubbell, assistant director (superintendent), has been acting director.

Foremen Should Not Dispense Acetylsalicylic Acid.—Newspapers reported on August 12 that Dr. J. Lynn Mahaffey, Trenton, state director of health, made a recommendation to the Ford Motor Company at Edgewater that it discontinue a recently established practice of allowing foremen to dispense aspirin (acetylsalicylic acid) to workers complaining of minor ailments. It was stated that the health director also recommended that the company revert to its old procedure of allowing workers complaining of minor ailments to visit on the company's time, first aid stations in the plant staffed with medical personnel.

Medical School to Open October 1.—The Essex College of Medicine, said to be the first institution of its kind in New Jersey, plans to open about October 1 in a three story building at Broad Street and Third Avenue, Newark, according to the *New York Times*. The facilities include an auditorium, twenty-five classrooms and laboratories. A prospective faculty of fifty members is available, it was stated. The state board of education recently ruled that the school might not issue the degree of doctor of medicine until it has been in existence two years. In a statement to the press, Samuel R. Herbst, registrar, is reported to have said "The board encouraged us to open on that basis. It's a testing period, a trial period that they wanted us to go through, and we'll open on that understanding." The registrar also stated that more than 200 applications, mainly from New Jersey residents, had been received, and that the institution would open as soon as 100 had been accepted. For the first four years only 100 students would be accepted each year, it was stated.

NEW YORK

Personal.—A surprise party was held for Dr. Christopher G. Parnall recently in celebration of his twentieth anniversary as medical director of the Rochester General Hospital, Rochester.

Physician Observes Ninety-Fifth Birthday.—Dr. Gerrit F. Blauvelt, Nyack, former president of the Rockland County Medical Society, observed his ninety-fifth birthday August 1. Dr. Blauvelt is the sole surviving incorporator of the Nyack Hospital.

Free X-Ray Service to Public.—The Ontario County Committee on Tuberculosis and Public Health plans to make available free roentgenograms of the chest to every one, newspapers reported. The plan is an expansion of the original one of limiting the service to industrial employees only. Tests will be made by a visiting mobile x-ray unit that will tour the county and will be available to any one wishing to do so.

Physicians Honored.—Dr. Festus M. Chaffee was given a dinner in the Middlesex Town Hall, August 1, for his forty years of service to the community.—The Wayne County Medical Society on August 8 gave a dinner in honor of four members who have completed fifty years in the practice of medicine. The physicians are Drs. George D. Winchell, Rose; Cyrus P. Jennings, Macedon; Samuel L. Houston, Wolcott, and Ralph Sheldon, Lyons.

Outbreak of Food Poisoning.—Ninety-two members of the staff at Strong Memorial Hospital, Rochester, became ill, August 17. Fifty-two were hospitalized and 40 others were unable to report for duty. An investigation disclosed that the outbreak was attributed to bacteria infected egg salad sandwiches which had been served to members of the staff. None had been served to the patients of the hospital. Among the persons ill were medical students, physicians and dietitians. The 40 less severe cases were among student nurses, who were treated at their homes, the *Rochester Times-Union* reported.

New York City

Louis Julianelle Dies.—Louis A. Julianelle, Ph.D., chief of the division of infectious diseases, Public Health Research Institute, died in Memorial Hospital for the Treatment of Cancer and Allied Diseases, August 12, aged 49. Dr. Julianelle received his Ph.D. at the University of Pennsylvania in 1922, subsequently serving there as instructor in bacteriology. After a number of years of service at the Hospital of the Rockefeller Institute, Dr. Julianelle joined the staff of Washington University School of Medicine, St. Louis, serving there from 1930 to 1942, when he went to New York.

The Lewis Cass Ledyard Fellowship.—Applications are now being accepted for the Lewis Cass Ledyard Jr. Fellowship by the Society of the New York Hospital. Three thousand dollars will be available as a stipend to an investigator in the fields of medicine and surgery or in any closely related field and about \$1,000 for supplies or expenses of the research. Preference will be given to younger applicants who are graduates in medicine and who have demonstrated fitness to carry on original research of high order. Applications should be received by the Committee of the Lewis Cass Ledyard Jr. Fellowship not later than December 15. It is expected that the award will be made by March 15, 1945. Additional information may be obtained from Dr. Eugene F. Du Bois, chairman of the committee, Society of the New York Hospital, 525 East 68th Street. The fellowship was established in 1939 by a gift from Mrs. Ruth E. Ledyard in memory of her late husband, Lewis Cass Ledyard Jr., a governor of the New York Hospital.

Course in Industrial Medicine.—The Long Island College of Medicine, Brooklyn, will conduct its third postgraduate course in industrial medicine October 16 to November 3 under the auspices of the department of preventive medicine and community health. The course intends to provide physicians engaged in full time or part time industrial practice, as well as those who wish to enter this field an opportunity to orientate themselves more fully to modern procedures in the rapidly developing specialty of industrial medicine. This year the course will place particular emphasis on postwar conditions and problems associated with the return of workers from military service. Although designed for graduate physicians, the course will be open to industrial executives, personnel workers, industrial nurses, hygienists, engineers and others interested in industrial health. The course will include afternoon and evening lectures and seminars at the college supplemented by morning clinics and demonstrations arranged in cooperating hospitals and industrial medical departments. Sections of the course will be devoted to medical administration in industry, industrial aspects of internal medicine, industrial surgery, occupational diseases and personal relations in industry, with emphasis on the medical aspects of personnel problems. Additional information may be obtained from Dr. Thomas D. Dublin, 248 Baltic Street, Brooklyn 2.

OKLAHOMA

Narcotic Violation.—Dr. William T. Huddleston, Konawa, pleaded guilty in the U. S. District Court at Muskogee, June 28, of a violation of the federal narcotic laws. The physician was sentenced to pay a fine of \$800 and was placed on probation for a period of five years.

The Leroy Long Memorial Lecture.—Dr. George M. Curtis, Columbus, Ohio, gave the Leroy Long Memorial Lecture in Oklahoma City, June 21, on "Surgery of the Spleen." The lecture is sponsored by the alumni and undergraduates of Phi Beta Pi as a memorial to the late Dr. Leroy Long, Oklahoma City, dean of the medical school from 1915 to 1931.

Annual Conference.—The Oklahoma City Clinical Society will hold its fourteenth annual clinical conference at the Biltmore Hotel, Oklahoma City, October 23-26. Among the speakers will be:

Dr. Nathaniel G. Alcock, Iowa City, urology.
Dr. O. Theron Clagett, Rochester, Minn., surgery.
Dr. Charles C. Denme, Kansas City, Mo., dermatology.
Dr. Lawrence P. Engel, Kansas City, surgery.
Dr. George P. Guibor, Chicago, ophthalmology.
Dr. Tinsley R. Harrison, Dallas, Texas, medicine.
Dr. Harold O. Jones, Chicago, gynecology.
Dr. Ralph A. Kinsella, St. Louis, medicine.
Dr. Hugh McCulloch, St. Louis, pediatrics.
Dr. Ralph H. Major, Kansas City, medicine.
Dr. William F. Mengert, Dallas, obstetrics.
Dr. Alan R. Moritz, Boston, pathology.
Dr. Henry H. Ritter, New York, surgery.
Dr. George E. Shambaugh, Chicago, otolaryngology.
Dr. James S. Sneed, Memphis, Tenn., orthopedic surgery.
Dr. Bruce K. Wiseman, Columbus, Ohio, medicine.
Dr. Herman L. Kretschmer, Chicago, President, American Medical Association.

PENNSYLVANIA

Foreign Nonprofit Organizations and Medical Service.—The Department of Justice of Pennsylvania has ruled that foreign nonprofit corporations cannot enter the state to provide or render medical services to individuals except when specifically authorized by statute, according to *Philadelphia Medicine*.

Schireson Obtains Injunction Against State Board.—A temporary injunction was recently issued by the Dauphin County Court restraining the state board of medical education and licensure from conducting a hearing on a citation against Dr. Henry J. Schireson, Philadelphia, to show cause why his license should not be revoked. The hearing was to have been held July 14.

RHODE ISLAND

Personal.—Paul J. Spencer of Butler Hospital, Providence, has been appointed secretary of the New England Hospital Assembly to succeed Gerhard Hartman, director of Newton Hospital, Newton, Mass., resigned.

Butler Hospital Observes Centennial.—Butler Hospital, Providence, will hold its second and final observance of its one hundredth anniversary on October 4. The program is intended to interest the lay public, and a special evening session will be held at the Rhode Island School of Design. Governor J. Howard McGrath is expected to attend the meeting. Other speakers will include:

Dr. Elhu S. Wing, Providence, president, state medical society, a message from the medical profession.
Clemens J. France, director, Rhode Island State Department of Social Welfare, an appreciation from social welfare.
Col. H. Edmund Bullis, A Hundred Years of Service in Mental Health.
Dr. Arthur H. Ruggles, superintendent, Providence, A Few Remarks on the Past, the Present and the Future of Rhode Island's Oldest Hospital.

GENERAL

Physician Needed in West Africa.—Dr. George W. Harley, who recently returned to this country because of an emergency health condition, announces that a physician is urgently needed in Ganta, Liberia, West Africa. The emergency was created when Dr. Harley, founder of the Ganta Mission, was compelled to return to the United States. The area to be served is inhabited by more than a million natives and 25 or 30 white missionaries. Physicians in contingent mission stations have gone one by one to join the United States armed forces. At the dispensary handled by Dr. Harley the work is now carried on with the aid of a school teacher, Miss Mildred Black, who is not even a nurse, and a couple of schoolboys who help in the treatment of about 200 patients with leprosy and assist with intramuscular and intravenous injections each week. These injections are mostly for yaws, trypanosomiasis, schistosomiasis and other skin diseases. The position is available to a doctor of medicine who has graduated at an approved medical school and who has had two years' internship or residency. The salary is moderate, with allow-

ances for wife and children; travel expenses will be paid. Communication from Dr. Harley indicates that the position offers experience in tropical medicine and includes facilities for research in trypanosomiasis and leprosy.

Accident Facts.—The National Safety Council has just brought out its 1944 edition of "Accident Facts," which presents a comprehensive report on accidents of all types. The booklet states that the 1943 accidental death toll was 97,500, an increase of about 2 per cent over 1942. Accidental injuries in 1943 totaled about 10,100,000, about 350,000 of which resulted in some permanent disability ranging from a finger amputation to permanent crippling. Accident costs totaled approximately \$4,900,000,000, including wage loss, medical expense, overhead costs of insurance, property damage in motor vehicle accidents and fires, and the so-called indirect costs of occupational accidents. Motor vehicle accidents accounted for 23,400, a 17 per cent decrease from 1942. Public nonmotor vehicle accidental deaths of civilians totaled 17,000, a 6 per cent increase over the previous year. There were 32,500 civilian home accident fatalities in 1943, an increase of 7 per cent over 1942. Deaths of civilians in occupational accidents totaled 18,000, or 3 per cent less than in 1942. Accidental deaths of military personnel in the United States accounted for 11,500 deaths, a 69 per cent increase over 1942. The most important single type of accidental death in 1943 was falls, replacing motor vehicle accidents, which had for twenty years resulted in the largest annual death total. Falls accounted for 27,400 deaths, giving a rate per hundred thousand of 20.3, an increase of 7 per cent over 1942. The total increase since 1933 amounted to 17 per cent.

American Hospital Meeting.—The annual convention of the American Hospital Association will be held at the Hotel Statler and Public Auditorium, Cleveland, October 2-6. The preliminary program includes the following speakers:

Thomas S. Gates, LL.D., President, University of Pennsylvania, Philadelphia, The Commission on Hospital Care.
Dr. Arthur C. Bachmeyer, director, University of Chicago Clinics, Hospital Trends.
Dr. Morris Fishbein, Editor, THE JOURNAL, The Physician and Public Health.
Dr. Julius L. Wilson, New Orleans, Tuberculosis, the Hospital and Public Health.

International College of Surgeons.—The ninth national assembly of the United States chapter of the International College of Surgeons will be held at the Benjamin Franklin Hotel, Philadelphia, October 3-5, under the presidency of Dr. Thomas A. Shallow, who will speak on "Radical Treatment of Carcinoma of the Esophagus." Included among the speakers will be:

Dr. George M. Piercol, Philadelphia, Rehabilitation.
Dr. Desiderio A. Roman, Philadelphia, The Classic Cesarean Section, with Analyses of 53 Cases Operated on by the Author.
Dr. Leonard Averett, Philadelphia, Vaginal Hysterectomy: Indication and Advantages.
Dr. Frances I. Seymour, New York, The Responsibility of the Surgeon in the Preservation of Human Fertility.
Dr. Roy W. Mohler, Philadelphia, An Analysis of the Indications, Results and Dangers of Complete and Supravaginal Hysterectomy.
Dr. Clifford B. Lull, Philadelphia, Caudal Anesthesia.
Dr. Karl F. Schaeffer, Milwaukee, Pentothol Sodium Anesthesia in Major Surgery and Its Dangers.
Dr. Charles M. Griffith, Washington, D. C., The Rehabilitation of Ex-Members of the Armed Forces by the Veterans Administration.
Capt. Howard H. Montgomery (MC), Rehabilitation in the Navy.
Major General George I. Lull, M. C. (Subject not announced).
Vice Admiral Ross T. McIntire, Surgeon General of the Navy (Subject not announced).
Dr. Thomas B. Noble Jr., Indianapolis, The Surgical Control of Obstructive Adhesions of the Small Bowel.
Dr. John E. Cannadai, Charleston, W. Va., The Cutis (Dermis) Graft Transplant.
Dr. Robert H. Ivy, Philadelphia, Principles of Skin Graft.
Dr. Lyman Weeks Crossman, New York, Refrigeration for the Preservation of Traumatized Tissue.
Dr. John Royal Moore, Philadelphia, Massive Bone Defects.
Dr. Curtis Lee Hall, Washington, D. C., Osteotomy for the Treatment of Ununited Fractures of the Femoral Neck.

Dr Austin T Moore Columbia S C Fractures of the Hip Joint Treatment with Adjustable Nails or Blade Plate Fixation
Dr Roger Anderson, Seattle (subject not announced)
Drs Harry F Bacon, Orville C Gass and William D Todhunter Philadelphia, Cancer of the Rectum and Pelvic Colon with Special Reference to Preoperative and Postoperative Treatment
Dr William Seaman Bainbridge, New York A Survey of Surgical Results in Cancer
Dr Albert A Berg New York, The Preservation of the Sphincter Ani in Radical Operation for Cancer of the Rectum
Dr Elmer Hess Erie Pa., The Indications for Transplantation of the Ureters with a New Surgical Technique
Dr Oswald Swinney Lowsley, New York, Plastic Operations on the Kidneys
Dr Rudolf Nissen New York A New Technique of Operation for Cysts of the Lung and for Chronic Spontaneous Pneumothorax
Dr Frederick M Allen New York, Surgical Shock and Its Treatment
Dr Richard H Lawler, Chicago Gastric Surgery
Dr Sebastian J Carnazzo, Omaha, Subtotal Gastric Resection for Peptic Ulcer
Dr Max Thorek Chicago, History and Practical Application of Tubo-vagular Gastrostomy
Dr Moses Behrend, Philadelphia Ulcerative Leiomyoma of the Stomach
Dr Asher Winkelstein New York The Relation of Gastric Acidity to Recurrent Ulcers After Partial Gastrectomy
Dr Otto De Muth, Vancouver, B C, Recent Developments of Biliary Surgery
Nicholas A Michels D Sc, Philadelphia Variations in the Arterial Blood Supply of the Liver, Gallbladder, Stomach, Duodenum and Pancreas
Robert Lich Jr and Ralph B Samson U S Public Health Service Reserve, A Method of Inguinal Herniorrhaphy
Miss Helen S Willard director, Philadelphia School of Occupational Therapy, Occupational Therapy in Rehabilitation
Dr William A Lell Philadelphia, Observation on the Bronchoscopic Insufflation of the Sulfonamides into the Tracheobronchial Tree
Dr Benjamin I Golden Elkins, W Va., Massive Single Doses of the Sulf Drugs
Dr Elias D Lawrence Paterson N J, Sphenous Vein Ligation
Dr Edmund B Spaeth, Philadelphia, Aneurysm of Circle of Willis from an Ophthalmological Standpoint
Dr Samuel R Skillern, Philadelphia, The Frontal Sinuses as the Path way of Infection to the Cranium and Its Contents
Dr Ben Robnett Dysart, Pasadena, Calif., Diabetic Gangrene Involving the Sinuses

The program will include a series of round table discussions and scientific and technical exhibits and motion pictures. On Wednesday evening the convocation address will be delivered by Dr Morris Fishbein, Chicago, Editor of *THE JOURNAL*, on "The Organization of American Medicine." The assembly dinner will be held Thursday evening.

FOREIGN

Dr. Aldo Castellani Reported Suspended from Rome Faculty—Dr Aldo Castellani, who formerly served as professor of tropical medicine at Tulane University of Louisiana School of Medicine and Louisiana State University Medical Center, New Orleans, is reported to be one of twenty five members of the faculty of the University of Rome who have been suspended. According to *Science*, the *Times*, London, states that the majority of these men had either been ministers in the fascist government or had held high appointments in the corporations.

Special Lectures—At the recent sixth annual meeting of the Royal Australasian College of Physicians, Sydney, Australia, a portrait of the first president of the college, Sir Charles Buckerton Blackburn, was unveiled. Special lectures delivered as a part of the meeting included the second G L Renne Memorial Lecture by Sir C Trent Champion de Crespigny, London, on "Torula Infection of the Central Nervous System" and the second Annie B Cuning Lecture by Dr C G McDonald on "Diet and Disease." Other speakers included Lieut Col J Erskine Sewell on "Notes on Scrub Typhus from the Observation of 500 Cases," Dr T M Greenaway, "Hyperinsulinism Due to Pancreatic Adenoma" and Dr S V Sewell, "The Results of Sympathectomy in the Treatment of Severe Cardiac Pain, Headache and So forth."—Dr Thomas L Hardy recently delivered the Croonian Lectures before the Royal College of Physicians of London on "Order and Disorder in the Large Intestine."

Report Dr Carrel Ousted—On August 28 the Associated Press reported that Dr Alexis Carrel, emeritus member of the Rockefeller Institute for Medical Research, New York, and associate member of the American Medical Association, had been dismissed from his position as director of the Vichy government's Foundation for the Study of Human Relations. The information was said to be broadcast over the Paris radio and further intimated that the foundation had been "notorious for its actions detrimental to the French nation." Dr Carrel, who is 71 years of age, is a native Frenchman who retained his citizenship despite many years spent in the United States. A newspaper report on August 30 indicated that Dr Carrel had been arrested by the French Forces of the Interior on charges that he had "founded his institute with Vichy support for the purpose of supplanting the great French universities,

and introducing fascism and Marxism to the students." It was further stated that the Petain regime donated funds freely to Dr Carrel's institute, the initial gift amounting to about \$800,000, with the intention of hiring away professors from the Sorbonne and other universities. It was further alleged that Dr Carrel tried to close university laboratories so that professors would have to come to his institute to earn their living.

Government Services

Charles Williams to Direct States Services

Dr Charles L Williams, who has been stationed in New Orleans as medical and district director for the U S Public Health Service district number 4 since July 1, 1940, was to have been transferred on August 16 to Washington, D C, as assistant surgeon general. He will be in charge of the Bureau of States Services (*THE JOURNAL*, Dec 11, 1943, p 983) and will be promoted to the rank of brigadier general.

Private Home Given to Public Health Service

Hilhome in Westchester County, New York, estate of the late Percy S Straus, became on August 11 the property of the U S Public Health Service, which will make it a convalescent home for merchant seamen and Coast Guardsmen. The presentation of the deed by Mrs Straus was made in a special ceremony in the headquarters of the U S Public Health Service in Washington, D C. In accepting the deed Dr Thomas Parran, Surgeon General, U S Public Health Service, is reported to have said that the home may be converted into a convalescent home with 75 beds and, subject to Presidential approval, will be the site of a permanent hospital under the postwar program of the public health service. The property includes a 112 acre tract partly in the town of Rye and partly in the town of Harrison and is located 4 miles north of Port Chester. Hilhome will be available for hospital use immediately and will be adapted for permanent hospital service. During the twenty-five years that it has been the home of the Straus family, more than a million dollars has been expended on the property above the original cost. Mr Straus was formerly chairman of the board of R H Macy and Company.

Funds for Public Works

The President, July 10, approved allotment of federal funds totaling \$1,412,488 for thirty war public works and services projects in seventeen states, including hospital and child care facilities and schools in war impacted communities. Major General Philip B Fleming, federal works administrator, announced. A grant of \$291,802 will match funds of the Sisters of St Francis for constructing and equipping a 100 bed hospital in Detroit to cost an estimated \$583,604. A second grant in the Detroit area is for \$30,800 for an addition to the Burton School in Royal Oak Township. Federal contributions of \$222,324 and \$199,886 go to the U S Public Health Service for continued assistance in the maintenance and operation of venereal disease hospital facilities in Chatham County and in Augusta, Ga., respectively. More than 2100 patients have been treated in these centers. A grant of \$75,700 was made to the Allegany Hospital of the Sisters of Charity in Cumberland, Md., providing for the dismantling and transporting of a demountable dormitory from Dublin, Va., and constructing, altering and equipping the building to provide training facilities for student nurses. A grant of \$34,500 will match an equal amount provided by the Medical College of Virginia, Richmond, for remodeling a part of St Philip Hospital in Richmond, to expand training facilities for 185 student nurses. Six California communities will receive funds for child care centers and for school maintenance. Other projects were approved in Alabama, Arizona, Idaho, Missouri, Oregon, North and South Carolina, Pennsylvania and Texas.

CORRECTION

Officers of Pathology Board.—The name of Major R Philip Custer, M C, was inadvertently omitted from the news item carrying the names of new officers of the American Board of Pathology (*THE JOURNAL*, August 12, p 1051). Major Custer was chosen trustee-at-large of the board.

The Rebuilding of Guy's Hospital

Guy's Hospital is known all over the world not only as a great teaching center but also for the advances in English medicine emanating from it. The clinician Jonathan Hutchinson once said "Diseases seem to have been made in order that Guy's physicians should discover them." No doubt he had in mind the eponymous diseases of Bright, Addison and Hodgkin, who were elder contemporaries of his. This famous hospital has been badly damaged by German bombs, but arrangements have already been made, thanks to the munificence of Lord Nuffield, to restore it with every modern equipment and to build a new college for students. The eighteenth century buildings, which have survived and are suitable for modern requirements, will be combined with new buildings. Now located in the country (whither bombing has made many of the London hospitals resort) is what is known as "Guy's U. S. A. Hospital," because it was started as a wartime measure largely by American help. It is thought that this should prove of great value in working out the bigger plan for a permanent country Guy's. Planning is not restricted to building. A closer fusion of the hospital with its medical and dental schools into a great teaching center is contemplated. Already new fields are opening up. A recent development, the York Clinic for Psychoneuroses, is the only one of the kind in the country associated with a teaching hospital. Guy's has the largest dental school, and it is hoped that arrangements can be made for every patient to receive not only expert dental treatment but also any other treatment necessary. It is also proposed to establish a university chair in dental medicine and to make a study of the relations between dental disease and disease processes in general.

Labeling of Foods to Protect the Public

The Ministry of Food has issued an order on food labeling which is intended to ensure wholesome quality and to make certain that the public gets what it expects. Under the new ruling, certain requirements must be met by the labels of all prepacked foods (those packed or made ready in advance for retail sale in a wrapper or container). The labels must show the name and address or registered trade mark of the person for whom the food is packed and the name or usual name of the food. Foods containing more than one ingredient must show the usual name of the ingredients in the order of the proportions in which they were used and the minimum quantity of food in the package. Foods claiming to contain vitamins or minerals are subject to special rules. Claims must not be made on the labels or in advertisements unless supported by a statement of the nature of the vitamin or mineral present and the quantity. Fruit and vegetables are exempt from this order unless canned or boiled.

The Accidental Discovery of Penicillin

In an address at the King's Chapel of the Savoy on Hospital Sunday (when donations for the hospitals are collected), Alexander Fleming, the discoverer of penicillin, delivered an address. The discovery, he said, illustrated the great value of the freedom to pursue research which was so prominent in the voluntary hospital and might be restricted under a more bureaucratic system. Like many bacteriologists, Professor Fleming related, he had many culture plates contaminated with mold spores which drop from the air, and, like every other bacteriologist, he had cast them out with suitable expressions of annoyance. But on this one occasion he did not, and peni-

cillin was the result. He noticed that the molds prevented growth of the culture for a small area. It seemed providential that the most powerful agent against septic infection was discovered at this time, when we were plunged into a bloody war. Penicillin has already done much to alleviate the sufferings of the wounded, Fleming stated, and will do more as the supply increases. In the last war the infected wounds of many soldiers remained open for six months or more, with frequent painful dressings. Now it is hoped that by the aid of penicillin they will not become infected at all or that, if they do, many will heal in a month or less.

The Site for Intramuscular Injections

In the correspondence columns of the *British Medical Journal* attention is called to the danger of using the gluteal muscles as a site for intramuscular injections. This practice is not only in vogue but is taught in our leading hospitals, it is stated by Prof. Grey Turner, who recalls that he pointed out its dangers as long ago as 1920. After the first world war he observed that several soldiers were victims of severe and persistent neuritis or paralysis of the great sciatic nerve as a result of injecting quinine solutions into the nerve instead of into the mass of the gluteal muscle. A case of death from sloughing also came to his knowledge. After the malaria epidemic in Ceylon there were at least 2 cases of severe secondary hemorrhage from the superior gluteal artery complicating abscess due to injecting quinine into the buttock. In 1941 A. W. Frankland stated in the *Journal* that if solutions of sulfapyridine are administered deeply into the gluteal region there is grave danger of injury to the larger branches of the sciatic nerve. He quoted 6 cases of foot drop with varying degrees of anesthesia, and also cases of gluteal paresis. Recently one of the larger provincial hospitals was forced to pay damages of several hundred pounds because a patient developed sciatic paralysis after an injection in the gluteal region.

Professor Turner again urges that the outer side of the thigh is the proper place for such injections. The vastus externus is a large muscle, is protected by the fascia lata and is not traversed by any important vessels or nerves. The muscular mass is of large capacity and as much as 500 cc. can be introduced into its substance, provided the injection is done slowly. The technic is simple, Professor Turner claims. A point on the middle of the outer side of the thigh is selected, and the hollow needle is thrust at right angles to the surface. It is enough to insert it just beneath the fascia lata—a point which can readily be determined by the sensation of yielding resistance after penetration or by introducing the needle to the average depth of about an inch. If the needle strikes the bone no harm is done, provided it is withdrawn about half an inch before injecting. If necessary, injections of small bulk may be made repeatedly in this situation. It is reasonable to vary the area of injection by starting near the top of the thigh and working down to about 3 inches above the knee; or the outer side of the other thigh may be used alternately. Injection of a particularly irritating solution or introduction of infection may result in abscess, but that is about the worst that can happen. The risk of phlebitis and generalized systemic infection associated with rigors is eliminated, Professor Turner says.

The *Army Medical Department Bulletin* also deals with the subject of intramuscular injection, particularly in battle casualties. The *Bulletin* points out that the injection should be made into healthy muscle. The gluteal muscles are perhaps most often chosen. They are extensive enough to absorb a good volume of fluid. It is important to keep clear of the sciatic nerve and related vessels. The upper and outer quadrant alone may be regarded as a suitable area for injection; it has a good thickness of muscle, lies well away from the sciatic nerve and is not pressed on as the patient lies in bed. Many other muscle groups are suitable. It is unnecessary to put a badly wounded

man to the discomfort of turning him on a stretcher simply to give an intramuscular injection into his buttock, the *Bulletin* states. The external thigh muscles, deltoid muscle and pectoral muscles are often more conveniently accessible. Indeed, any large muscle away from important vessels or nerves may be used.

AUSTRALIA

(From Our Regular Correspondent)

May 20, 1944.

Problems of Anthropology in the Pacific

While the war is still raging in the Pacific it may seem premature to consider proposals for the future government and development of native races in the South Pacific islands. Yet, assuming that Australia's interest and responsibility in relation to mandated territories will be retained and possibly extended when the war is over, it is obvious that the welfare of the territory natives, whose friendship and assistance in the present conflict are of inestimable value to the Allied nations, must be taken into account in planning for postwar reconstruction.

This question is raised by J. W. Burton in a pamphlet entitled "Brown and White in the South Pacific," published by the Australian Institute of International Affairs. He declares that the impact of the present catastrophic war will affect the life and social order of the native races to an extent which at this stage cannot be determined, but it is obvious that the results will be deep and far reaching.

When Australians read of the heroic and unselfish part taken by the native stretcher bearers of Papua and New Guinea in the campaign against the Japanese, few give a thought to the effects of the war on social life of the island natives, the disruption caused in homes and villages, the demoralizing effect on the younger natives, the problem of restoring native agriculture and normal conditions of community life when peace returns.

Burton's pamphlet deals first with the native culture in the Pacific—a very old culture with roots that go deep into the past. "One may live for weeks in a native village," he says, "and feel its rhythm and charm, enjoy its laughter and gaiety, watch its colorful ceremonies and yet not suspect that the simplest actions and most commonplace habits have a long ancestry behind them and that every part of the common life is regulated by almost imperceptible rules of conduct." He states too that the South Sea social organization has been classed by some as communistic, although not in any marxian sense, and this element is admittedly present, for the life of the village is assuredly based, perhaps quite unconsciously, on the principle of "each for all and all for each." In Fiji, for instance, all land is held by the mataqali, or clan, and can never be alienated unless the mataqali itself dies out. While every man has his own house (in Fiji usually of an excellent type), no one can sell his house to another. Like the land, it belongs to the people as a whole, and the occupant has only the use of it.

It is pointed out that under this system there was no danger of property falling into a few hands, as with us. Mutual ownership of property prevented accretions of wealth and thereby restricted temporal power. No man ever went hungry, except for some visitation of nature, such as drought or flood; no one went unemployed, although there was abundant leisure.

With the introduction of the plantation system by white men came the indenture of native labor. It is true, says Mr. Burton, that the indenture system has its good side as far as the native is concerned. On the other hand, from the moral point of view, life on the plantations is far from ideal. Large numbers of men, separated for years from their women-folk and from the healthy influence of children, contract vices such as gambling, thieving and general irresponsibility, and return to exercise a bad influence on the village.

As to the evidence of the effects of the present war on the native life and social order, Mr. Burton says "In areas, particularly in the southeastern Pacific, where the actual devastation of war has not been felt, there are serious repercussions. The presence of tens of thousands of European servicemen, with plenty of money to spend and abundant leisure, has had a profound and immediate effect on native economy. There has come such an abundance of wealth that it has resulted in many places in natives neglecting their gardens and villages; they are content to do a little washing for the troops or sell a few curios at ridiculous prices and then spend their money in buying tinned meats and preserved fruits from the trader's store."

There is too, Mr. Burton adds, a serious disregard for the village authority, and the young girls have had their heads turned by the attentions of random admirers while their own men are away at other theaters of war. "There is no vivid imagination required to sense the dangers here," he says. "The case of those islands, particularly the Solomons, Papua and New Guinea, where the ravages of war have been so terrible, is even worse. No estimate can be made of the physical damage done. Hundreds of people have been killed, thousands have been torn away from their villages, and, although they have won a great name as stretcher bearers and carriers, no one may estimate the rupture of the social fabric of their lives."

There is evidence that both United States and Australian armies are conscious of these problems and are taking action to overcome them.

Australian Reaction to British Criticism of Medical Students' Training

The report of the planning committee of the Royal College of Physicians aroused interest here. The report stated that the average medical graduate has defects chiefly attributable to the manner of his training. He tends to lack curiosity and initiative. His powers of observation are relatively undeveloped, his ability to arrange and interpret facts is poor and he lacks precision in the use of words. In short, his training, however satisfactory it may have been in the technical sense, has been unsatisfactory as education.

Increase of scholarships as a method of overcoming financial barriers to the profession has the defect of compelling a boy to specialize in order to pass examination, at the expense of general education, especially in activities that develop personality and character. University education should be absolutely free, not only in medicine but in all other subjects. Allocation to universities would be on the merit of character plus ability, instead of wealth. Methods whereby the medical course itself can be improved include curtailment of certain traditional subjects, such as botany and topographic anatomy and, preeminently, division of medical education into two categories—the undergraduate course, which shall be general and unspecialized and designed to provide for doctors as a whole, and the postgraduate course, catering to special needs of gynecology, x-rays and other highly technical branches.

Dr. B. T. Zwar, deputy chancellor of Melbourne University and president of the Royal Melbourne Hospital, said that experience in the last war had shown that graduates of Australian medical schools compared very favorably with those from English schools, while our graduates who went to England were very highly regarded there. Dr. Zwar said he agreed, however, that there was insufficient preliminary general education before university courses were begun. Up to this year Melbourne University had accepted students at 16 years of age; now it is 17, but he felt that was still rather young. In England the General Medical Council had laid down that no medical student could register until within three months of his eighteenth birthday. Dr. Zwar was particularly

glad to note that the planning committee of the Royal College of Physicians had said that allocation to universities should be on "the merit of character, plus ability, instead of wealth." He said he had always advocated that some regard should be paid to the character of a student entering a profession; that was done in various American university medical schools, and the system had worked quite satisfactorily.

BRAZIL

(From Our Regular Correspondent)

SÃO PAULO, July 22, 1944.

Treatment of Chronic Osteomyelitis with Penicillin and Surgery

At the last meeting of the National Academy of Medicine a paper was presented by Dr. Mauricio Gudín on the treatment of 2 cases of chronic osteomyelitis in which surgery, under conditions of "integral asepsis of the environment," was associated with the use of penicillin. Dr. Gudín constructed, several years ago, a closed and entirely aseptic operating room, which he uses for his daily work at the Beneficência Portuguesa Hospital of Rio de Janeiro. This whole aseptic operating technic has also been adopted by a few surgeons of Paris, where the system was considered worth while. In Dr. Gudín's first case the illness began thirteen years earlier, and eight operations had been performed. Recently the patient had been treated, without result, with twenty-five intramuscular injections of penicillin prepared at the Oswaldo Cruz Institute. After the operation in the integrally aseptic room the patient received several local, intramuscular and intra-arterial injections of the same penicillin. The wound healed completely in seven days. The second patient became ill in 1937 and had been operated on three times by another surgeon. Dr. Gudín operated once more, this time under conditions of integral asepsis, and the wound was maintained opened. On the seventh day the dressing was undone in the aseptic room and it was ascertained that the wound was in good condition. On the fourteenth day the wound was again examined and a secondary suture was done. On the twenty-first day healing was judged complete. The treatment by penicillin was the same as in the first case.

Iodized Table Salt to Combat Goiter

Central Brazil has a great area where goiter is endemic, and iodine deficiency in several parts of this area has been ascertained. In order to help correct this situation Mr. João Alberto, coordinator of economic mobilization, signed a special order with the following main provisions: 1. All table salt to be consumed in the areas recognized as deficient in iodine shall be industrially processed to contain the amount of iodine judged appropriate by the Division of Food of the Office of the Coordinator. 2. The product to be immediately sold under the name of "iodized table salt" shall contain 10 mg. (15 grains) of iodine per kilogram (2.2 pounds) of table salt. 3. The Division of Food will furnish technical assistance to table salt producers to insure the effectiveness of this order. The order also established a limit on the increase in price to be charged for iodized table salt.

Relief of Pain in Renal Colic

Prof. Luis Surraco and Dr. Lockart have presented a new treatment for renal colic. According to their recent publication in Montevideo they proposed the inhalation of amyl nitrite as an unproved means to relieve the pain.

The pain in renal colic arises from a spasm of the smooth muscular fibers, surrounding the ureter as well as the visceral ducts, and provokes regional contracture, to which there is added a ureteral distention above and a zone of ischemia below, the whole acting through appropriate stimuli on a special state of hyperreflectivity of the aortic-renal plexus.

It is understood that the therapy in crisis, in order to be useful, should take the form of a sedative for the hypersensi-

tivity, an antispasmodic for the hypertonicity, a vasodilator favoring arterial irrigation and venous depletion. Responding to these demands, Surraco and Lockart have employed amyl nitrite, which has a well known action against the cardio-arterial spasm and which in renal colic produces the triple vasodilator, hypotensive and analgesic action through total intervention of the splanchnic nerves.

Immediately following inhalation they observed, together with the usual vascular phenomena, a complete and lasting cessation of the spontaneous pain, disappearance of the contracture of the abdominal wall through concomitant action on the striated muscular fiber and frequently a stimulation of diuresis. This quick action of the medicament is an important help in diagnosis in doubtful syndromes.

The immediate action of the amyl nitrite may be maintained and prolonged by employing glyceryl trinitrate after a few hours, repeating it according to the circumstances in the course of the first twenty-four or forty-eight hours.

Brief Items

Since the beginning of the war and the shortage of some medicinal products, the culture of *Mentha piperita* and the extraction of peppermint oil are being developed in São Paulo, Paraná and the other southern states of Brazil. At the price of \$30 per kilogram of crystallized menthol, as set by the United States government for the importation of the drug, the production of menthol is one of the best paid extractive industries. A free booklet on the culture of the plant is being distributed by the division of information of the Department of Agriculture.

Ten years ago on June 6, Dr. Miguel Couto, professor emeritus of medicine at the University of Rio de Janeiro, died at the age of 72. Dr. Couto had a large private practice in Rio de Janeiro and has been considered by some the greatest Brazilian doctor of the present century. The Brazilian Academy of Medicine held a special meeting to commemorate this anniversary.

The National University of Rio de Janeiro is a semiautonomous organization financially supported in large part by the federal government. The government has recently bought a large plot of land known as the Valqueire Park in a northern suburb of Rio de Janeiro, in which will be constructed the new buildings of the university.

Dr. Augusto Paulino Jr. has been elected a member of the National Academy of Medicine. Dr. Paulino is professor of surgery at the University of Rio de Janeiro.

The Brazilian Society of Ophthalmology recently held a meeting in which papers on endocrinologic problems in ophthalmology, tumors and refractive changes in diabetes were discussed. The most important papers were presented by Dr. Evaldo Campos, Dr. Orlando Cyrino and Dr. Sylvio de Campos.

Marriages

WILL BYRN ALSUP JR., Dublin, Ga., to Miss Martha Ham McRae of Charlotte, N. C., in Colorado Springs, Colo., August 4.

SAMUEL RICHARD STAGGERS, West Point, Miss., to Miss Sophy Malone Tilley of Durham, N. C., August 12.

JOHN JAY OSBORN, Garrison-on-Hudson, N. Y., to Miss Anne Mary M. Kidder of New York, August 6.

JAY EDWIN STOECKEL, Scranton, Pa., to Dr. CATHERINE M. ROTH of Roanoke, Va., July 22.

GRAHAM BURT BLAINE JR. to Miss Patricia Smallwood, both of New York, August 5.

HENRY T. SIMMONDS to Mrs. Edythe Graeber Wetzel, both of Shamokin, Pa., July 28.

ROBERT L. DILTS, Fort Wayne, Ind., to Miss Virginia Lewis of Indianapolis, July 28.

JOHN T. MANNING, Muskegon, Mich., to Miss Betty F. Letts of Flint, July 29.

Deaths

Charles Hartwell Cocke ☉ Asheville, N. C.; Cornell University Medical College, New York, 1905; served an internship in the Presbyterian Hospital, New York, in 1906-1907; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians, serving once as chairman of the board of governors and vice president in 1942, 1943 and 1944; in 1926 vice president of the Medical Society of the State of North Carolina; past president and secretary of the Buncombe County Medical Society; in 1932 vice president of the Southern Medical Association and in 1937 chairman of its section on medicine; fellow and former vice president of the American College of Chest Physicians; member and in 1934 vice president of the American Clinical and Climatological Association; member of the American Trudeau Society, American Association of the History of Medicine, American Sanatorium Association, Southern Interurban Clinical Club and the National Tuberculosis Association; corresponding member of the International Union Against Tuberculosis; attending physician, Asheville Mission Hospital and the Biltmore (N. C.) Hospital; consulting physician to the Patton Memorial Hospital, Hendersonville; one of the medical directors and attending physician, Zephyr Hill Sanatorium; member of the chamber of commerce; served as secretary and heart and lung consultant to the medical advisory board during World War I; died August 3, aged 62, of coronary occlusion.

Frederick Brown Moorehead ☉ Chicago; Rush Medical College, Chicago, 1906; professor of oral surgery and head of the department of oral and plastic surgery and oral pathology at the University of Illinois College of Dentistry; formerly associate clinical professor of surgery (oral and dental) at his alma mater; chairman of the Section on Stomatology, American Medical Association, 1914-1915, 1915-1916; member and in 1926-1927 president of the American Association of Oral and Plastic Surgeons; member of the Institute of Medicine of Chicago, Chicago Pathological Society and the Chicago Historical Society; fellow of the American College of Surgeons; specialist certified by the American Board of Plastic Surgery; joint author of "Pathology of the Mouth"; consulting plastic surgeon, Illinois Central Railroad System; consulting oral and plastic surgeon, Home for Destitute and Crippled Children; attending oral and plastic surgeon, Presbyterian Hospital, where he died August 29, aged 68, of peritonitis due to perforated gastric ulcer and bronchopneumonia.

Herman Elwyn Pearse, Bonner Springs, Kan.; St. Louis College of Physicians and Surgeons, 1888; honorary member of the Kansas Medical Society; past president of the Missouri State Medical Association and the Jackson County (Mo.) Medical Society; fellow of the American College of Surgeons; a founder and at one time professor of abdominal surgery at the Kansas City College of Physicians and Surgeons; formerly professor of surgery at the Kansas City Post-Graduate Medical School and Hospital; health director of Kansas City, Mo., 1925-1926; a member of the staff of St. Luke's Hospital, of which he had been a founder, and of St. Joseph, St. Mary's and Kansas City General hospitals, where in 1916 he had been chief of staff; died June 10, aged 84, of myocarditis.

Alfred A. Kent Sr., Winter Park, Fla.; Jefferson Medical College of Philadelphia, 1885; formerly a practitioner in Lenoir, N. C.; member and past president of the Medical Society of the State of North Carolina; organizer and once president of the Caldwell County (N. C.) Medical Society; for many years a member of the North Carolina State Board of Medical Examiners and for two years president; served as a member of the North Carolina State Board of Health and the North Carolina state legislature; an organizer and former president of the Citizens Building and Loan Association and president of the First National Bank of Lenoir; died August 11, aged 85.

William H. German, Chicago; Michigan College of Medicine, Detroit, 1883; member of the Illinois State Medical Society and the American Association of Railway Surgeons; served as a major in the Illinois National Guard; formerly member of the Morgan Park elementary, high school and library boards; for twenty-two years secretary of the Calumet Park district; since 1902 local surgeon for the Chicago, Rock Island and Pacific Railroad; died in the Wesley Memorial Hospital July 31, aged 89, of chronic myocarditis, chronic nephritis and bilateral lobar pneumonia.

Smylie Scott Anderson, Hammond, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1906; served as health officer of Hammond; died June 25, aged 66.

Thomas Rufus Aycock ☉ Monroe, Ga.; University of Georgia Medical Department, Augusta, 1909; served as acting president and secretary of the Walton County Medical Society; on the staff of the Walton County Hospital, Walker Park; died in St. Joseph Infirmary, Atlanta, August 5, aged 62, of heart disease following an operation.

Charles Wesley Banks, East Orange, N. J.; Bellevue Hospital Medical College, New York, 1890; formerly city pathologist; served as chief of staff and chief surgeon of St. Mary's Hospital in Orange for many years; for many years in charge of the infirmary of the Thomas A. Edison, Inc., plant in West Orange; died July 21, aged 77, of carcinoma of the bladder.

John Banks, Hamilton, Ga.; Atlanta School of Medicine, 1911; died May 16, aged 65.

Blaine B. Barton, Markleysburg, Pa.; Maryland Medical College, Baltimore, 1905; member of the Medical Society of the State of Pennsylvania; died July 8, aged 64, of cerebral hemorrhage.

Burton Wayne Bivins, Wonehoe, Wis.; Chicago College of Medicine and Surgery, 1904; Spanish-American War Veteran; died in Chetek June 7, aged 68, of coronary thrombosis.

Stanislaus N. Borowiak, Buffalo; University of Buffalo School of Medicine, 1908; served as president of the board of education of Buffalo; secretary-treasurer of the Polish Medical Association, 1910-1914; in 1933 received the Polonia Restituta medal from the Polish government for aid in the restoration of Poland; died in the Millard Fillmore Hospital July 11, aged 61, of myocardial failure and coronary arteriosclerosis.

Oliver Preston Bourbon ☉ Los Angeles; Kansas City (Mo.) Hahnemann Medical College, 1908; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; formerly assistant professor of surgery (ophthalmology), College of Medical Evangelists; at one time lecturer on physiology at his alma mater; on the staffs of the Methodist Hospital and the California Hospital, where he died April 25, aged 80, of coronary thrombosis.

Christopher William Brown, Brooklyn; Long Island College Hospital, Brooklyn, 1903; member of the Medical Society of the State of New York; on the staff of the Bushwick Hospital for many years; during World War I served as a captain with the thirteenth Regiment Coast Artillery; died in the Long Island College Hospital July 7, aged 64, of carcinoma of the stomach with metastases to the spine.

Emerson Marrs Bushnell ☉ Black Lick, Pa.; University of Vermont College of Medicine, Burlington, 1903; president of the Indiana County Medical Society in 1936; school director and bank president; served on the staff of the Indiana Hospital, Indiana, Pa.; died April 21, aged 67, of coronary disease.

William Aaron Cashion, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; a captain in the medical corps of the U. S. Army during World War I; formerly associated with the U. S. Veterans Administration; died July 1, aged 53, of coronary occlusion due to cardiorenal vascular disease.

Charles Eli Caylor ☉ Bluffton, Ind.; Kentucky School of Medicine, Louisville, 1893; in 1895 president of the Wells County Medical Society; a charter member of the Bluffton Rotary Club; member of the Southern Medical Association; chief of staff of the Caylor-Nickel Clinic, which he founded, and of the Clinic Hospital, where he died July 5, aged 74, of a skull fracture and other injuries received in an automobile accident.

Emily Clark Charles, New York; New York Medical College and Hospital for Women, Homeopathic, New York, 1894; subsequently served at her alma mater as lecturer on diseases of children, assistant to the chair of diseases of children, secretary of the faculty, associate professor of diseases of children, professor of materia medica and dean; died in the Franklin County Hospital, Greenfield, Mass., July 9, aged 80, of a strangulated femoral hernia.

William Fladger Clark, Tampa, Fla.; Emory University School of Medicine, Atlanta, 1922; died in the Tampa Municipal Hospital July 11, aged 49, of bronchopneumonia and general septicemia.

Daniel Crosby ☉ Oakland, Calif.; Cooper Medical College, San Francisco, 1898; past president of the Alameda County Medical Association; fellow of the American College of Surgeons; health officer of Oakland, 1918-1920; past president of

the Insurance Association of Approved Hospitals; on the staffs of the Providence and Peralta hospitals, Oakland, and the Alameda Hospital, Alameda; died at his home in Piedmont July 15, aged 69, of coronary thrombosis.

Nelson Park Davis @ Pittsburgh; University of Pittsburgh School of Medicine, 1909; associate professor of surgery at his alma mater; fellow of the American College of Surgeons; on the staff of the Mercy Hospital; died July 7, aged 58, of cerebral hemorrhage.

Lester Cornelius Diddy, Paxton, Ill.; Chicago College of Medicine and Surgery, 1907; member of the Illinois State Medical Society; past president of the Ford County Medical Society; died July 11, aged 61, of coronary heart disease.

Hugh Victor Du Bois, Niota, Tenn.; Chattanooga (Tenn.) Medical College, 1904; died July 7, aged 64, of heart disease.

Harry Edward Dunlop @ Pelham, N. Y.; University of the City of New York Medical Department, New York, 1886; an Affiliate Fellow of the American Medical Association; died in the Gallagher Nursing Home, Mount Vernon, July 14, aged 80, of transverse myelitis and uremia.

Elihu Noble Elliott, Chicago; College of Physicians and Surgeons, Chicago, 1883; member of the Illinois State Medical Society; died June 29, aged 82, of carcinoma of the prostate with metastasis, pyelocystitis and cerebral arteriosclerosis.

Ralph Waldo Emerson, Owensville, Ind.; Eclectic Medical Institute, Cincinnati, 1898; died July 3, aged 74, of heart disease.

William Albert Fisher @ Chicago; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; at one time president and professor of ophthalmology at the Chicago Eye, Ear, Nose and Throat College; formerly professor of clinical ophthalmology at the University of Illinois College of Medicine; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; died July 31, aged 84.

Thomas Francis Foley, Buffalo; University of Buffalo School of Medicine, 1904; for many years staff physician in the child hygiene division of the city health department; a captain in the medical corps of the U. S. Army during World War I; medical examiner at the Attica State Prison; died July 11, aged 68, of pulmonary edema and dilatation of the heart.

Frederick Lewis Forker, Binghamton, N. Y.; University of the City of New York Medical Department, 1885; served as a member of the board of education; on the staffs of the Binghamton City and Our Lady of Lourdes Memorial hospitals; died July 11, aged 83, of arteriosclerosis.

William Hodskin Gale, St. Johns, Mich.; Jefferson Medical College of Philadelphia, 1901; formerly secretary and treasurer of the Clinton County Medical Society; served in the medical corps of the U. S. Army during World War I; in 1910 appointed to the U. S. Board of Pensions; for many years county health officer; on the staff of the Clinton Memorial Hospital; served as district surgeon for the Grand Trunk Railroad; died June 30, aged 74, of cardiorenal disease.

John Asa Gibbons, Mitchell, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1898; died in the Dunn Memorial Hospital, Bedford, July 6, aged 71, of carcinoma of the rectum.

John Louis Gilleland, Pullman, Wash.; American Medical College, St. Louis, 1903; member of the Washington State Medical Association; formerly on the staff of St. Ignatius Hospital, Colfax; died June 5, aged 69, of carcinoma of the prostate and Parkinson's disease.

Thomas Leverett Gingold, New Haven, Conn.; Columbia University College of Physicians and Surgeons, New York, 1919; formerly police surgeon and alderman; served on the staff of the Grace Hospital, where he died July 6, aged 49, of carcinoma of the pancreas.

Faustine Graves, Piney Flats, Tenn.; Tennessee Medical College, Knoxville, 1894; died July 13, aged 76, of myocardial failure and Parkinson's disease.

J. Edward Harmon, Pine Knot, Ky.; Hospital College of Medicine, Louisville, 1905; died in St. Anthony's Hospital, Louisville, June 29, aged 65, of hypertensive cardiovascular disease.

John Edward Harris, Winchester, Va.; Medical College of Virginia, Richmond, 1900; secretary-treasurer of the Medical Society of Northern Virginia and of the Winchester Memorial Hospital; died May 30, aged 69.

Atticus Greene Haygood @ Downey, Calif.; University of Nashville (Tenn.) Medical Department, 1891; Vanderbilt University School of Medicine, Nashville, 1891; a captain in the medical corps of the U. S. Army during World War I; examiner for the Selective Service Board; on the staff of the Methodist Hospital, Los Angeles; a charter member and past president of the Kiwanis Club; died in the Downey Community Hospital June 27, aged 73, of bronchopneumonia and acute gastroenteritis.

Edward Lathrop Hill Jr., Jacksonville, Ill.; St. Louis University School of Medicine, 1933; member of the Illinois State Medical Society; formerly an intern at St. Louis City Hospital and resident in neuropsychiatry at the City Sanatorium in St. Louis; first lieutenant in the medical reserve corps of the U. S. Army not on active duty; health officer in charge of the McDonough-Fulton bicoounty health unit of the state health department with headquarters in Macomb; died in the Barnes Hospital, St. Louis, aged 37, of myelogenous leukemia.

Joseph Harrison Humphrey @ St. Louis; Washington University School of Medicine, St. Louis, 1901; served as director of hygiene for the board of education; died in the Evangelical Deaconess Home and Hospital June 23, aged 67, of cerebral embolism.

John Charles Kamp, Saugerties, N. Y.; University of Buffalo School of Medicine, 1895; member of the Medical Society of the State of New York; health officer since May 1924 with jurisdiction over the consolidated health district of Saugerties; served on the staff of the Kingston Hospital, Kingston; died June 18, aged 84, of arteriosclerosis.

Edwin Jerome Kauffman, Marion, S. D.; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1906; member of the South Dakota State Medical Association; formerly councilman; on the staffs of the Methodist State Hospital, Mitchell, and the Sioux Valley Hospital, Sioux Falls, where he died May 1, aged 60, of coronary thrombosis.

Theophilus Kubricht, Wallis, Texas; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; also a minister; died in a sanatorium in Houston May 28, aged 80.

Charles Labash, Passaic, N. J.; Chicago Medical School, 1926; member of the Medical Society of New Jersey; died in St. Mary's Hospital June 26, aged 61, of cirrhosis of the liver.

Virgil Alfred Lea, Gloster, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; died in the Marion Butler Memorial Hospital, Liberty, August 6, aged 63, of injuries received in an automobile accident.

Thomas B. W. Leland, San Francisco; University of California Medical Department, San Francisco, 1894; formerly county and city coroner; served as a lieutenant commander in the U. S. Navy during World War I; died June 28, aged 74.

Frederic Michael Lemen, Buffalo; University of Buffalo School of Medicine, 1905; member of the Medical Society of the State of New York; on the staff of the Millard Fillmore Hospital; died June 24, aged 64, of leukemia.

Patrick F. Martin, Emmitsburg, Md.; University of Maryland School of Medicine, Baltimore, 1900; member of the Medical and Chirurgical Faculty of Maryland; served as coroner in eastern and western health districts of Baltimore; for many years resident physician at the Mount St. Mary's College; died June 18, aged 67, of uremia.

Hubert Burns Marvin @ Binghamton, N. Y.; University of Buffalo School of Medicine, 1907; fellow of the American College of Physicians; examiner for draft board number 453; member of the examining board during World War I; on the staff of the Susquehanna Valley Home and the Binghamton City Hospital, where he died June 20, aged 64, of pneumonia.

Roy Cowles McDaniel @ Portland, Ore.; Medico-Chirurgical College of Philadelphia, 1905; fellow of the American College of Surgeons; served as secretary-treasurer of the Eastern Oregon District Medical Society; first vice president of the Oregon State Medical Society, 1909-1910; member of the staffs of St. Vincent's, Emanuel and Good Samaritan hospitals; died June 16, aged 62, of coronary occlusion.

Gertrude Minthorn, Newport, Ore.; State University of Iowa College of Medicine, Iowa City, 1910; formerly a medical missionary in India; died June 28, aged 62, of chronic endocarditis.

Edwin Pendleton Moon, Wetumpka, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; member of the Medical Association of the State of Alabama; served as state physician for prison number 1 and the tuberculosis hospital; died June 10, aged 67, of arteriosclerosis.

Nathan Vernon Noble, St. Mary's, Ohio; Starling-Ohio Medical College, Columbus, 1911; member of the Ohio State Medical Association; an officer in the medical corps of the U. S. Army during World War I; on the staffs of the Memorial and St. Rita's hospitals; died June 26, aged 55, of coronary thrombosis.

Carlton V. Norcross, Butte, Mont.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1887; died May 20, aged 80.

Clifford Seeley Page, Sisseton, S. D.; Yale University School of Medicine, New Haven, Conn., 1896; formerly coroner of Clark County, Neb., and camp surgeon for the Civilian Conservation Corps in New Ulm, Minn.; physician for the Indian agency; died in the Peabody Hospital, Webster, May 15, aged 68.

Howard Ashley Pardee, Upper Montclair, N. J.; University of the City of New York Medical Department, 1880; retired in 1934 as medical director of the United States Life Insurance Company, a position he held for many years; died July 23, aged 85, of acute congestive heart failure secondary to chronic myocarditis and arteriosclerosis.

Lester Claude Pepper @ Sidney, Ohio; Starling Medical College, Columbus, 1898; formerly member of the legislative committee, past president, vice president, delegate and secretary of the Shelby County Medical Society; served as county coroner and as examining physician for the local Selective Service Board; died in the Wilson Memorial Hospital June 23, aged 68, of cerebral hemorrhage.

Carl Anton Platou, Valley City, N. D.; Maryland Medical College, Baltimore, 1912; member of the North Dakota State Medical Association; served during World War I; on the staff of the Mercy Hospital; died in Pompano, Fla., May 22, aged 56, of coronary occlusion.

Hyman Leon Ratnoff @ New York; Cornell University Medical College, New York, 1906; on the staffs of the Beth-El and Kingston Avenue hospitals; died June 25, aged 62, of coronary thrombosis.

Volney E. H. Reed, Austin, Texas; Missouri Medical College, St. Louis, 1881; served as president of the bank in Holland for many years; formerly health officer of Milan County; died June 3, aged 84.

Clarence William Robertson @ Jamestown, N. D.; Rush Medical College, Chicago, 1915; on the staffs of the Jamestown and Trinity hospitals; died May 22, aged 53, of coronary thrombosis.

Walter C. Robinson, Atlanta, Ga.; Southern Medical College, Atlanta, 1881; honorary member of the Medical Association of Georgia; died June 17, aged 88, of cerebral embolism.

William Taylor Salmon, Duncan, Okla.; University of Tennessee Medical Department, Nashville, 1892; formerly associated with the Indian Service; died June 26, aged 75, of cranial hemorrhage and hypertension.

Charles Matthew Scott, Bluefield, W. Va.; University College of Medicine, Richmond, 1901; member of the West Virginia State Medical Association; fellow of the American College of Surgeons; past president of the county board of health; founder and head of St. Luke's Hospital; established the St. Luke's Nurses Training School; for eight years secretary of the state board of examiners for nurses; died in the University Hospitals, Iowa City, August 17, aged 65, of pneumonia following an operation.

John Sidney Sharp, Grenada, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1895; member of the Mississippi State Medical Association; for many years a member of the state board of health; member of the Grenada Clinic since its organization; on the staff of the Grenada General Hospital; chief surgeon in the area for the Illinois Central Railroad; died August 5, aged 72, of carcinoma of the prostate.

Isaac Judah Silverman @ Washington, D. C.; University of Melbourne Faculty of Medicine, Australia, 1911; professor of clinical psychiatry at the Georgetown University School of Medicine; member of the American Psychiatric Association; fellow of the American College of Physicians; on the staff

of the Gallinger Municipal Hospital; died August 6, aged 55, of acute myocardial infarction (posterior) and arteriosclerotic heart disease.

Rufus Southworth, Glendale, Ohio; Miami Medical College, Cincinnati, 1904; served as associate professor of therapeutics at the University of Cincinnati College of Medicine; served in the medical corps of the U. S. Army during World War I; formerly a medical missionary in China; made a memorable trip around the world in the schooner *Yankee*; formerly on the staff of the Cincinnati General Hospital; died in the Christ Hospital, Cincinnati, June 14, aged 65, of cerebral hemorrhage.

Vivienne Eu Gene McMains Spencer, Sterlington, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1930; served on the staff of St. Francis' Sanitarium, Monroe; died in El Paso, Texas, June 26, aged 39, of military tuberculosis.

Edward Charles Stoeltje, Rosebud, Texas; Louisville (Ky.) Medical College, 1897; member of the State Medical Association of Texas; killed in an automobile accident in Galveston June 20, aged 71.

Henry Marshall Swift @ Cape Elizabeth, Maine; Harvard Medical School, Boston, 1900; assistant in neuropathology at Tufts College Medical School, Boston, 1907-1908; formerly professor of neurology at the Bowdoin Medical School, Portland; served during World War I; member of the American Psychiatric Association and the New England Society of Psychiatry; at one time on the staff of the Danvers Insane Hospital, Danvers, Mass.; past president of the Portland Medical Club; died August 18, aged 72.

Gaston E. Trosclair, Thibodaux, La.; University of the South Medical Department, Sewanee, Tenn., 1903; died in St. Joseph Hospital June 30, aged 67, of heart disease, nephritis and hypertrophic cirrhosis of the liver.

Thomas Freeman Turner @ Macon, Mo.; Washington University School of Medicine, St. Louis, 1925; served an internship at St. Luke's Hospital, Kansas City; county physician; aged 42; drowned in Macon Lake June 28 when the motor boat in which he was riding capsized.

Elbert Lycurgus Watson @ Newport, Ark.; Columbia University College of Physicians and Surgeons, New York, 1900; past president of the Arkansas State Board of Health; president of the Jackson County Medical Society; a captain in the medical corps of the U. S. Army during World War I; at one time mayor of Newport; served as county health officer; physician for the Missouri Pacific Railroad Company; died June 3, aged 68.

Myron La Verne White @ Coffeyville, Kan.; Duham Medical College, Chicago, 1901; served during World War I; died in the Mercy Hospital, Independence, June 4, aged 71, of cirrhosis of the liver and bronchopneumonia.

James Frederick Young, Danbury, Conn.; Columbia University College of Physicians and Surgeons, New York, 1913; served in the medical corps of the U. S. Army during World War I; died June 27, aged 55.

KILLED IN ACTION

Elmer Norval Carter, Huntington, W. Va.; Medical College of Virginia, Richmond, 1937; member of the West Virginia State Medical Association; served an internship at the Scott and White Hospital in Temple, Texas, a residency in psychiatry at the Spencer State Hospital, Spencer, and a residency in medicine at the Chesapeake and Ohio Hospital; commissioned a first lieutenant in the medical corps of the Army of the United States July 7, 1942 and began active duty on Aug. 10, 1942; in 1943 ordered to England, where he was assigned to hospital duty; promoted to captain; battalion surgeon in the Twenty-Ninth Division; killed in action in Normandy June 19, aged 32.

CAPT. ELMER N. CARTER
M. C., A. U. S., 1911-1944

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices or cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

Amlsogen.—In December 1943 J P Hoff, Berwyn, Ill., and the A N Baker Advertising Agency, Inc., Chicago, stipulated with the Federal Trade Commission that they would discontinue the following misrepresentations in the advertising of this product: That it will have any effect on asthma except to the extent that it may afford palliative relief from the paroxysms of this disease, that it will relieve hay fever or its symptoms, or that the product is free from opiates or narcotics. They further agreed not to disseminate any advertisement which fails to reveal that the product should not be used in excess of the dosage recommended, that frequent or continued use of it may be habit forming or cause nervousness, restlessness or sleeplessness and that the product should not be used by persons suffering from high blood pressure, heart disease, diabetes or thyroid trouble. It was provided, however, that such advertisements need only contain the statement, "Caution Use Only as Directed" if the labeling directions contain a warning to the same effect.

Buxton's A Special Compound.—This is marketed by a Hope Buxton, trading as Buxton Medicine Company, Abbot Village, Maine. In November 1943 this person stipulated with the Federal Trade Commission to cease representing that the product has been approved by a federal agency, that it is a remedy or cure for sciatica, arthritis, neuritis, diseased liver, stomach or kidneys, that it eliminates uric acid from the system, overcomes acidity, strengthens the heart, normalizes the kidneys or bladder, purifies the blood or is a treatment for indigestion or stomach trouble.

Cramer Chemical Company's Preparations.—The concern in question, located at Gardner, Kan., stipulated with the Federal Trade Commission in December 1943 that it would discontinue the following misrepresentations: That "Nitrotran" is the best known or most universally used germicide in the United States, produces complete sterilization in 90 seconds, checks or stops bleeding other than capillary bleeding from superficial skin lesions, draws the torn, jagged edges of a wound together, stops sore throat, assists in the prevention of influenza, or may be relied on for quick and safe recovery from all skin conditions, that "Cramer's Athletic Stringent for Gargle" is effective in checking or preventing influenza, tonsillitis or like disorders, that "Cramer's Athletic Liniment" has special penetrating powers or reaches into muscular or other tissues to any significant degree, that "Cramer's Dextrose Tablets" will produce quick energy in the sense of capacity for more intense physical exertion, stimulate an athlete to greater performance, enable him to win more games, or afford immediate relief from hay fever or asthma, that "Cramer's Athletic Hair Oil" prevents "shower bath baldness" or any other kind of baldness, that "Iso Pine" is a suitable preparation for sterilizing surgical instruments, that "Cramer's Athletic Effervescent Alkaline Powder" relieves acid condition of the system or has any significant effect on the acid base balance of the body, that "Athletic Ointment" has any therapeutic effect on boils or performs any function in the healing process, that "Athletic Red Hot Ointment" relieves deep seated pain or affords adequate relief from sprains, that "Athletic Analgesic Balm" relieves congestion, that "Athletic Foot Ointment" is an effective treatment for athlete's foot or ringworm except in mild cases, that "Athletic Inhalant" effectively relieves sinus trouble or forms a protective coating against bacteria, that "Cramer's Cold Tablets" have any appreciable effect in preventing common colds, or that "Cramer's Athletic Alkaline Powder" relieves nausea or stomach sickness, regard less of the nature or cause thereof. The respondent also agreed to cease using the word "Antiseptic" as part of the trade name or designation of "Cramer's Athletic Antiseptic Powder," or indicating in any way that the nostrum has antiseptic properties.

Dr Gray's Foot Bath Powder.—In November 1943 S W Ward, trading as Ward & Sons, Chicago, entered into a stipulation with the Federal Trade Commission to discontinue the following misrepresentations in advertising the product: That it is used by physicians, hospitals or sanatoria, that it is a result of scientific research or a study of foot ailments, that statements in the advertising have been made by, or are quotations from, the literature of the United States Public Health Service or that the latter or any other agency of the government has endorsed or recommended the use of this powder; that a package of it has a greater value than the price at which it is regularly sold, that its price is limited as to time, or that the powder draws poison from the feet, has curative or healing powers, or destroys germs. Ward further agreed to discontinue the representations that no other products are as effective as his powder is in the treatment of athlete's foot, itching, broken skin, open sores and blisters, that its use will prevent athlete's foot, or that the coloring of the skin caused by the powder destroys infection.

Elastic Rupture-Guard.—This is put out by a T E Brooks, trading as the Rupture Guard Company, Marshall, Mich. In December 1943 Brooks and Ralph L Wolfe & Associates, Inc., an advertising agency stipulated with the Federal Trade Commission that they would discontinue representations that the device in question may be properly fitted to one's personal requirements when ordered through the mails, will hold the rupture securely or comfortably in any position of the body, will assist nature in strengthening the muscles or in closing the hernia opening, or that it is the only device of its kind, further, they will cease representing that the use of the device will eventually enable one to go without a truss or will correct or cure rupture, that it will stay in position under all conditions of use, that it is more natural or comfortable than other trusses, or that satisfaction in using it is guaranteed, unless the terms of the guaranty are disclosed.

Sar-Tol Cough Syrup, Cough Drops and Nose Drops.—On Dec 8 1943 the Federal Trade Commission reported that it had accepted a stipulation from O B Whitaker, trading as the O B Whitaker Manufacturing Company, Joplin, Mo. In this he agreed to cease representing that his preparations, whether used alone or in combination, prevent or cure colds, have any curative effect on the underlying factors which cause colds, or cure throat irritations, prevent fatigue, maintain health or build in building body resistance. Further, he agreed to cease representing that Sar-Tol Cough Drops neutralize tobacco, onion or other odors. Also, Whitaker agreed to discontinue any advertisement which did not conspicuously warn that frequent or excessive use of the Nose Drops may cause injury to the lungs, nervousness, restlessness or sleeplessness, and should not, except on competent advice, be given to infants or young children, or be taken by persons suffering from high blood pressure, heart disease, diabetes or thyroid trouble. It was provided however, that such advertisements need only contain the statement "Caution Use Only as Directed" if and when the directions in the labeling contain a warning to the same effect.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated DDN] and foods, F N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment, (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Arabian Oil.—Standard Drug Company, Inc., Spartanburg, S C Shipped Feb 28 and March 13, 1941. Composition essentially a mixture of soap, ammonia, turpentine and water. Misbranded because the ammonia and turpentine present might be irritating to the skin, particularly if applied with rubbing, and also to eyes or mucous membranes, whereas label did not warn against this. Further misbranded because label falsely represented the product as a cure, treatment or preventive of pain incident to rheumatism, lame back, stiff joints, croup, swellings, wounds, and some other disorders.—[DDN J, FDC 805, December 1943]

Chmax C & P R.—Standard Drug Company, Inc., Spartanburg, S C Shipped Feb 28 and March 13, 1941. Composition essentially water, alcohol, chloroform and plant drugs, including capsicum. Misbranded because of false and misleading label representations for the product as a cure, treatment or preventive of pain in the bowels, cramp, colic and diarrhea.—[DDN J, FDC 805, December 1943]

Gloria Tonic Tablets.—John A Smith Company, Oconomowoc, Wis. Shipped Oct 20, 1941. Composition in each tablet 0.77 gram of iron, 3.64 grams of sodium salicylate, 0.003 gram of colchicin, and extract of cascara sagrada in an undeclared amount. Adulterated because strength differed from that which it was represented to possess, namely, in each tablet 1 grain of reduced iron, 5 grains of sodium salicylate and 1/20 grain of colchicin. Misbranded because directions on label did not provide for sufficient medication to constitute a treatment for gout, because, though a laxative, it failed to warn adequately that product should not be taken when symptoms of appendicitis were present, such as abdominal pain, nausea and vomiting and that frequent or continued use might result in dependence on laxatives, also misbranded because statement "Tonic An Allevial (sic) Treatment Useful in Gout" was false and misleading, since the tablets, when used as directed did not constitute a tonic or treatment for gout.—[DDN J, FDC 762, September 1943]

Royale Agar and Oil with Phenolphthalein.—Vital Laboratories, Union City, N J Shipped Jan 7 and March 21, 1942. Composition an emulsion containing mineral oil and phenolphthalein. Misbranded in that it bore no labeling containing adequate directions for use, or the warning that it should not be taken when nausea, vomiting, abdominal pain or other symptoms of appendicitis are present, or the caution that frequent or continued use might result in dependence on laxatives. Further misbranded because name and place of business of manufacturer, packer or distributor were not given, or an accurate statement of the quantity of the contents or the common or usual name of each active ingredient.—[DDN J, FDC 758, September 1943]

CANCER SAID TO BE CAUSED BY A SINGLE INJURY

To the Editor:—I am interested to note your editorial of August 12 on the matter of claims for disability said to have resulted from cancer caused by a single injury. In my opinion this editorial is timely but scarcely goes far enough. Traumatic cancer attracted my interest for a rather brief period following the death of the late Dr. James Ewing. Dr. Ewing had been interested in this matter for years and at his death a number of unfinished cases were turned over to me for completion.

In the course of hearings in these cases I acquired an exceedingly bad taste both for certain members of the legal profession and for members of the medical profession who seemed to me to be quite willing to testify to almost anything for a fee. I likewise learned to distrust the type of referee who is so afraid of possible injustice to a claimant that he tends to make awards in the face of incompetent evidence, and I believe he actually practices sociology rather than medicine. He rewards the "deserving" laborer at the expense of the insurance carrier and in so doing uses supposedly scientific medicine to further his notion of proper social behavior.

As for medical testimony, it appears to me that (1) such testimony can be purchased at a price or (2) those individuals who testify are hopelessly ignorant of the commonly known facts of cancer pathogenesis, which in turn is the result either of bad teaching in the cancer field or of dependence on casual statements heard in medical schools or encountered in textbooks on the subject. Lastly, it would oftentimes seem that the supposed expert doesn't take the trouble to reason at all. Let me illustrate: The same surgeon who will testify that mammary cancer has resulted from a single trauma will at the least provocation operate for a benign lesion of the breast and would never think of warning a patient that because of his operative trauma, which usually greatly exceeds the casual industrial trauma, she should give heed to the possibility that she will develop a cancer of the breast. The same surgeon who will do all sorts of orthopedic jobs involving chiseling into bone or insertion of such objects as ice tongs or pins or screws may testify that a blow which has left no real signs has caused an osteogenic sarcoma, although he never thinks his surgery will do so nor has he ever warned a patient with the severest form of bone trauma—a fracture—to be on the lookout for a possible sarcoma. A man testifies that a blow has caused a soft part sarcoma and yet that man and his colleagues throughout the world will do hundreds of thousands of appendectomies involving the cutting of abdominal wall musculature and observe no tumors. Another says that a malignant melanoma has followed a pin prick and yet no melanoma has ever followed the millions of venipunctures for complement fixation tests or intravenous medication. A third will say that testis cancer is the result of single trauma although the same tumor, histologically indistinguishable, appears in the ovary and no one assigns that to trauma. As far as I know I have never seen a cancer which I could logically and irrevocably assign to single trauma and, even more important than that, I do not know that any one has ever observed the development of a process which could be called "precancerous" after a trauma. The absurd efforts made in our compensation courts to emphasize the severity of traumas rests on the nonsensical point of view that there is some dividing line between the degree of trauma which will or will not cause cancer, under the popular supposition that the metabolic changes which make a cell a cancer cell require a few additional dynes for their complete florescence.

Some means should be found to exclude these figments of imagination from our compensation courts and place such claims

in the hands of a truly expert commission—not composed of individuals who have nothing else to do or who have political friends either within medicine or without—and make the findings of this commission binding on the compensation referee, thus avoiding time wasted at hearings, questions and insults from cheap lawyers, and the mental anguish resulting from having to listen to the testimony of ignorant doctors, that in itself, judged by medicolegal standards, might be deemed a sufficient cause for development of a glioma in the expert. I tried this in a way. That is, I wrote a few letters to people who should have been interested and didn't get anywhere and am unable to wage a one man war on the racket. It will certainly be hard to break, for, under the law, compensation is profitable to claimant, physician and lawyer, and of course in the end the public foots the bill.

FRED W. STEWART, M.D., New York.

Acting Director, Memorial Hospital for the
Treatment of Cancer and Allied Diseases.

Society Proceedings

American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 8-12. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Hospital Association, Cleveland, Oct. 2-6. Mr. George P. Bugbee, 18 East Division St., Chicago, Executive Secretary.

American Pediatric Society, Atlantic City, N. J., Sept. 25-27. Dr. Hugh McCulloch, 325 N. Euclid Ave., St. Louis 8, Secretary.

American Public Health Association, New York, Oct. 3-5. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Roentgen Ray Society, Chicago, Sept. 24-29. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.

Association of American Medical Colleges, Detroit, Oct. 23-25. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Association of Military Surgeons of the United States, New York, Nov. 2-4. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

Colorado State Medical Society, Denver, Sept. 27-29. Dr. John S. Bouslog, 537 Republic Bldg., Denver 2, Secretary.

Delaware, Medical Society of, Lewes, Sept. 11-12. Dr. W. O. La Motte, 601 Delaware Avenue, Wilmington, Secretary.

District of Columbia, Medical Society of the, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.

Indiana State Medical Association, Indianapolis, Oct. 3-5. Mr. T. A. Hendricks, 23 East Ohio St., Indianapolis 4, Executive Secretary.

Inter State Postgraduate Medical Association of North America, Chicago, Oct. 17-20. Dr. Arthur G. Sullivan, 16 N. Carroll St., Madison, Wis., Managing Director.

International College of Surgeons, U. S. Chapter, Philadelphia, Oct. 3-5. Dr. Desiderio Roman, 250 South 17th St., Philadelphia, Secretary.

Kentucky State Medical Association, Lexington, September 18-20. Dr. P. E. Blackerby, 620 S. Third St., Louisville, Secretary.

Michigan State Medical Society, Grand Rapids, Sept. 17-29. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Medical Society, Peoria, Ill., Sept. 27-28. Dr. Harold Swenberg, 510 Main St., Quincy, Ill., Secretary.

Omaha Mid-West Clinical Society, Omaha, Nebraska, Oct. 23-27. Dr. J. D. McCarthy, 1036 Medical Arts Bldg., Omaha 2, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Sept. 19-21. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Radiological Society of North America, Chicago, Sept. 24-29. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.

Virginia, Medical Society of, Richmond, Oct. 23-25. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Sept. 18-20. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Cerebral Hemorrhage Following Exertion in Hot Weather by Syphilitic Workman.—The workman, a Negro about 40 years of age, had syphilis in the tertiary state. The court nevertheless states that he enjoyed good health prior to the date of the industrial accident here discussed. On May 1, 1942, a "very warm" day, he had been unloading lumber from boxcars. About 7 p. m. he became overheated and had a dizzy feeling but continued to work another hour until his work day was finished. He was sick at home all night but returned to work next morning, when he became unconscious and was unable to begin work. Subsequently he suffered a cerebral hemorrhage which resulted in paralysis of his left side. He was denied compensation under the Florida workmen's compensation act and appealed to the circuit court, Leon County, which affirmed the denial of compensation. He then appealed to the Supreme Court of Florida.

The Florida workmen's compensation act, said the Supreme Court, so far as here pertinent, provides as follows:

"Accident" shall mean only an unexpected or unusual event, happening suddenly. . . . Where a preexisting disease is accelerated or aggravated by an accident arising out of and in the course of the employment, only acceleration of death or the acceleration or aggravation of disability reasonably attributable to the accident shall be compensable.

On just what precise reason the trial court denied compensation is not clear. Presumably the employer and his insurance carrier must have argued that Davis's disability was due solely to the syphilitic condition and that there was no causal connection between the exertion of employment and the disability. The Supreme Court concluded that Davis was entitled to compensation on the theory that the exertion of his employment had accelerated or aggravated his syphilitic condition. The court relied, among other cases, on *Crowley's Case*, 223 Mass. 288, 111 N. E. 786. The Massachusetts statute, said the Supreme Court, was similar to the Florida statute to be construed. In that case also the employee had syphilis but, being dormant, it left his ability unimpaired to carry on his work. Exertion of employment, apparently, was followed by paralysis or insanity and total disability. The employer and his insurance carrier contended that the workman could not recover under the Massachusetts workmen's compensation act because of the preexisting syphilitic condition. The court there said.

The statute prescribes no standard of fitness to which the employee must conform, and compensation is not based on any implied warranty of perfect health, or of immunity from latent and unknown tendencies to disease, which may develop into positive ailments, if incited to activity through any cause originating in the performance of the work for which he is hired. What the legislature might have said is one thing, what it has said is quite another thing, and in the application of the statute the cause of partial or total incapacity may spring from and be attributable to the injury just as much where undeveloped and dangerous physical conditions are set in motion producing such result as where it follows directly from dislocations, or dismemberments, or from internal organic changes capable of being exactly located. *Madden's Case*, 222 Mass. 487, 111 N. E. 379.

Recovery of compensation by a claimant, continued the Florida court, is not conditioned on good or perfect health. The statute here considered does not require a health certificate or require the workman to be free from disease at the time he was employed or injured. It is reasonable to assume that a workman has physical infirmities and takes them, if any, with him to his employment. The employer accepts the workman in such physical condition as he finds him and assumes the risk of a disease condition aggravated by injury. Compensation is not made to depend on the condition of health of the workman but on an injury which is a hazard of employment. The controlling principle of law is succinctly expressed by Schneider on Workmen's Compensation Law, ed. 2, vol. 1, p. 517, par. 138, viz:

Aggravation of Preexisting Condition—"Likewise the courts, consistent with the theory of workmen's compensation acts, hold with practical uniformity that, where an employee afflicted with disease receives a personal injury under such circumstances as that he might have appealed to the act for relief on account of the injury had there been no disease involved, but the disease as it in fact exists is by the injury materially aggravated or accelerated, resulting in disability or death earlier than

would have otherwise occurred and the disability or death does not result from the disease alone progressing naturally, as it would have done under ordinary conditions, but the injury aggravating and accelerating its progress, materially contributes to hasten its culmination in disability or death there may be an award under the compensation acts."

The Supreme Court accordingly, in effect, ordered an award of compensation in favor of the workman.—*Davis v. Arlt Const. Co.*, 18 So. (2d) 255 (Fla., 1944).

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the Examining Boards in Specialties were published in THE JOURNAL, Sept. 2, page 49.

BOARDS OF MEDICAL EXAMINERS

- ALABAMA: Montgomery, Oct. 24-26. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery.
- ARIZONA: Phoenix, Oct. 3-4. Sec., Dr. J. H. Patterson, 526 Security Bldg., Phoenix.
- ARKANSAS: Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison.
- DELAWARE: Dover, Oct. 10-12. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.
- DISTRICT OF COLUMBIA: Washington, November. Sec., Commission on Licensure, Dr. G. C. Rubland, 6150 E. Municipal Bldg., Washington.
- IDaho: Boise, Jan. 8-11. Dir., Bureau of Occupational Licenses, Mrs. Lela D. Painter, 355 State Capitol Bldg., Boise.
- ILLINOIS: Chicago, Oct. 10-12. Supt. of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.
- INDIANA: Indianapolis, Jan. 3-5. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 301 State House, Indianapolis 4.
- IOWA: Iowa City, Sept. 25-27. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.
- KANSAS: Nov. 2-3. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.
- KENTUCKY: Louisville, Sept. 11-13. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville.
- MARYLAND: Homocapital, Baltimore, Dec. 1-3. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.
- MICHIGAN: Detroit, Sept. 25-27. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.
- MISSISSIPPI: Jackson, Oct. 16-17. Asst. Sec., Dr. R. N. Whitfield, Jackson.
- MISSOURI: St. Louis, Sept. 18-20. Sec., State Board of Health, Dr. James Stewart, State Capitol Bldg., Jefferson City.
- MONTANA: Helena, Oct. 2-4. Sec., Dr. O. G. Klein, First Natl Bank Bldg., Helena.
- NEBRASKA: Omaha, Sept. 26-28. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.
- NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. D. G. Smith, 77 Main St., Nashua.
- NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.
- NORTH CAROLINA: Raleigh, Sept. 11-12. Sec., Dr. W. D. James, Hamlet.
- NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 412 S. 3rd St., Grand Forks.
- OHIO: Examination Columbus, Sept. 26-29. Endorsement, Columbus Oct. 3. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.
- OKLAHOMA: Oklahoma City, Sept. 16. Sec., Dr. J. D. Osborn, Jr., Frederick.
- SOUTH CAROLINA: Charleston, Sept. 11-13. Sec., Dr. N. B. Heward, 1529 Blandina St., Columbia.
- SOUTH DAKOTA: Pierre, Jan. 16-17. Sec., Medical Licensure, State Board of Health, Dr. G. Cottam, Pierre.
- TENNESSEE: Memphis and Nashville, Sept. 20-22. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis 3.
- TEXAS: Dallas, Nov. 15-17 and Dec. 19-21. Sec., Dr. T. J. Crouse, 918 20 Texas Bank Bldg., Dallas 2.
- UTAH: Salt Lake City, Sept. 13-15. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.
- VERMONT: Burlington, Sept. 12-14. Sec., Dr. F. J. Lathiss, Richfield.
- VIRGINIA: Richmond, Sept. 19-22. Sec., Dr. J. W. Preston, 30 1/2 Franklin Rd., Roanoke.
- WEST VIRGINIA: Charleston, Oct. 2-4. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.
- WISCONSIN: Endorsement Milwaukee, Sept. 18-19. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

* Basic Science Certificate required

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

- CONNECTICUT: New Haven, Oct. 14. Address, State Board of Health Arts, 250 Church Street, New Haven 10.
- DISTRICT OF COLUMBIA: Washington, Oct. 23-24. Sec., Commission on Licensure, Dr. G. C. Rubland, 6150 E. Municipal Bldg., Washington.
- FLORIDA: Gainesville, Nov. 4. Final date for filing application is Oct. 20. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.
- IOWA: Des Moines, Oct. 10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.
- MICHIGAN: Ann Arbor and Detroit, Oct. 13-14. Sec., Miss Elise LeBeau, 101 N. Walnut St., Lansing.
- NEBRASKA: Omaha, Oct. 3-4. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.
- NEW MEXICO: Santa Fe, Feb. 12. Sec., Miss Marion M. Pifer, State Capitol, Santa Fe.
- OREGON: Portland, Nov. 4. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.
- TEXAS: Memphis and Nashville, Sept. 25-26. Sec., Dr. O. W. Haman, 874 University Ave., Memphis.
- WISCONSIN: Madison, Sept. 23. Sec., Prof. R. N. Pauer, 132 W. Wisconsin Ave., Milwaukee 3.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Archives of Dermatology and Syphilology, Chicago
49:389-478 (June) 1944

Keratitis Blennorrhagica Without Gonorrhea (Reiter's Disease?). W. F. Lever and G. M. Crawford.—p. 389.

Chromoblastomycosis: Report of Case from Continental United States and Discussion of Classification of Causative Fungus. C. H. Binford, G. Hess and C. W. Emmons.—p. 398.

*Intensive Ambulatory Therapy of Syphilis: Thirty Day Mapharsen Technic. S. Goldblatt.—p. 403.

Ulcerative Diphtheria of Skin: Sporadic and Epidemic Types Observed in Haifa, Palestine. S. Gill.—p. 408.

*Hereditary Ectodermal Dysplasia: Report of Case, with Experimental Study. Z. Felsner.—p. 410.

Localized Myxedema in Association with Hypertthyroidism. J. C. Amersbach and B. Kane.—p. 415.

Fixed Erythema Due to Sulfanilamide with Gradually Lessening Sensitivity. A. Dostrovski and F. Sagher.—p. 418.

Coal Tar in Dermatologic Preparations. J. G. Downing, L. M. Ohmart and G. Di Cicco.—p. 421.

Bullous Lichen. Sclerosus et Atrophicus: Its Relation to Bullous Scleroderma. C. R. Anderson.—p. 423.

Cutaneous Absorption: II. Value of Petrolatum, Anhydrous Wool Fat and Other Bases in Percutaneous Absorption of Topically Applied Cottonseed Allergen. A. Walzer and S. S. Sack.—p. 427.

*Contact Dermatitis from Cold Permanent Waving. J. B. Howell.—p. 432.

Cutaneous Leishmaniasis (Oriental Sore): I. Time Required for Development of Immunity After Vaccination. D. A. Berberian.—p. 433.

Thirty Day Mapharsen Technic in Syphilis.—Goldblatt

gave 60 mg. of mapharsen intravenously dissolved in 5 cc. of sterile distilled water for thirty successive days. A total of 1,800 mg. of mapharsen was thus administered without adjuvant therapy. An unselected group of 107 patients with syphilis of all types, was treated by this intensive consecutive thirty day mapharsen method. The serologic reactions, which were positive in 81 per cent of the total group before treatment, showed a decided and continuing reduction in titer. On termination of the treatment positive serologic reactions were noted in 55 per cent, two months later in 35 per cent. Follow-up investigations from three to six months after the treatment indicated that the reactions of 20 per cent remained positive. No significant changes were observed in the formed or chemical constituents of the blood. Electrocardiographic examination revealed no deleterious effect on cardiac function, either immediately or remotely. Roentgenographic examination of the cardiovascular system indicated no progressive or toxic sequelae. Retreatment was carried out for the 3 patients with serologic relapse. Two with severe meningovascular involvement were subjected to fifteen attacks of induced fever concurrent with the hyperintensive therapy without untoward reaction. It was found possible to administer sulfonamide compounds for the treatment of intercurrent disease without interrupting the intensive mapharsen therapy. Complete healing of all the lesions of infectious syphilis required an average of ten days. A gain in weight and increased appetite and feeling of well-being were noted in the large majority of patients. No mucocutaneous relapse or neurorecurrence developed. This therapy appears to be nontoxic. Hospitalization is not required; the treatment is inexpensive and does not disrupt the economic life of the patient.

Hereditary Ectodermal Dysplasia.—Felsner shows that the inheritance of hereditary ectodermal dysplasia is not as clearcut as was believed. The history of his patient with this disorder revealed sex linked inheritance in the family tree, with male patients and female conductors. Eccrine glands were practically absent on the face and abdomen. Their number on the extremities was decreased to 5 to 7 per cent of the normal

number. Apocrine sweat glands were abundant in the axillas, on the upper part of the chest and on the perimamillary areas. The patient's insensible perspiration, at rest in a room temperature of 73 F., was normal. Atropine sulfate in a dose of 0.5 mg. subcutaneously did not change it. The intradermal injection of a 1:100 solution of acetylcholine bromide produced only a few isolated spots of sweating on the patient's forearm, as contrasted with the decided response of a normal control subject. In the heat chamber the body temperature of the patient rose rapidly whereas the body temperature of normal persons did not change under similar conditions. The term "hypohidrotic" is suggested as being more accurate than "anhidrotic" for the described type of ectodermal dysplasia. The absence of eccrine glands is not necessarily complete in spite of hyperthermia at high external temperatures.

Contact Dermatitis from Cold Permanent Waving.—

Howell reports that a woman experienced burning and stinging sensations over the sides of her neck, face and ears the afternoon after she had received her first cold permanent wave. The next morning she noted redness of the areas. When she was in the office the following day a mild dermatitis venenata type of eruption, consisting of slight swelling, diffuse redness, pruritus and in some areas fine vesiculation, was noted. The dermatitis reached its maximum extent within seventy-two hours and subsided by the end of the sixth day. Patch tests on 3 normal controls with 1 per cent concentrations of the shampoo, the preliminary lotion, the waving compound, the neutralizing solution and mixtures of these chemicals failed to evoke any reactions. Contact tests were then applied to the forearm of the patient one month after the dermatitis of her face, neck and ears had healed. On two different occasions a positive reaction followed within twenty-four hours the application of the preliminary lotion. No reactions were observed following contact tests with the waving compound, the neutralizing liquid or the shampoo. This case is an example of an eczematous contact dermatitis following within twenty-four hours a "cold permanent wave." Unquestionably this patient was already sensitive to some ingredient in the preliminary lotion, since patch tests elicited positive reactions on two different occasions. Sensitization due to previous contacts with the allergen present in the preliminary solution or a closely related chemical took place without the patient's knowledge. Reexposure to this substance when she received a cold permanent wave precipitated the allergic response.

Contributions to Plastic Surgery During 1943. L. A. Peer.—p. 537.

Injection of Tympanum for Chronic Conductive Deafness and Tinnitus Aurium.—According to Trowbridge, injection of the tympanum as a method of treatment in deafness was first suggested and used by Gray in 1934 at the Middlesex Hospital in London. Gray advocated this therapy for otosclerosis and employed thyroxin as the medium of injection.

Results with thyroxin therapy have not been altogether encouraging. Trowbridge sought an agent which would incite a sterile inflammation with subsequent absorption of the scar tissue, cicatricial bands and adhesions that interfere with the normal functioning of the conductive mechanism. The therapeutic value of ethylmorphine hydrochloride in removing pupillary exudates and in absorbing interstitial corneal deposits has long been known. It acts as a vasodilator and lymphagogue, stimulating the vascular and lymphatic circulation of the eye and producing dilatation of these vessels. The drug produces analgesia, which counteracts the discomfort of the injection and of the subsequent inflammation. Improvement in hearing occurred in 18 of 22 patients selected for this type of therapy. In 4 patients no improvement was obtained. Lessening of the tinnitus occurred in 6 and loss of tinnitus in 3 of 9 patients with associated tinnitus aurium. All of the patients were ambulatory and continued their usual daily routines without interference from the injections. Secondary reactions were negligible. Only transient vertigo occurred in several cases, disappearing within fifteen minutes after the injection. The improvement in hearing was demonstrated by audiometric studies as well as by the testimony of the patients themselves.

Malaria Mortality and Morbidity in 1942.—Malaria mortality data by states and counties for the United States in 1942 show a continued improvement over previous years. Only eight states had a rate of 1.0 or more per hundred thousand and only four counties had a rate of 25.0 or more. The malaria morbidity data, as reported by bureaus of vital statistics of several states, continue to be unreliable when tested against the expected ratios of deaths to cases. In mildly endemic territory such as the malarious areas of the United States have become it is estimated that there were between 236,000 and 590,000 cases in 1942 as compared with 278,000 to 695,000 in 1941.

Fibrin Foam as Hemostatic Agent in Neurosurgery.—Ingraham and his associates show that in the course of fractionation of human blood plasma large quantities of human fibrinogen and thrombin become available. Bering has prepared from these materials a substance designated "fibrin foam." The product is composed of a porous mass of fibrillar fibrin with macroscopic air spaces. When the foam is moistened, fluid rapidly enters the air spaces. It then becomes rubbery and shrinks to a certain extent. If the moistening agent is a solution of human thrombin, the foam becomes an effective hemostatic agent. While the fibrin foam and thrombin may be used in many forms of surgery, the authors' experiences are limited to neurosurgery. In this field it has proved the most satisfactory hemostatic agent available. For use in the operating room two bottles are provided. One contains sterile fibrin foam and the other thrombin in the dry state. Thrombin is dissolved in 30 cc. of sterile isotonic solution of sodium chloride. Pieces of the fibrin foam are then placed in the thrombin solution, after which the material is ready for use. For application to bleeding surfaces a piece of appropriate size is cut and held firmly against the tissue. This is usually best accomplished by covering it with a cotton patty and applying suction for a moment. When the patty is removed, the fibrin foam remains adherent to the tissue surface. The authors found that fibrin foam with

thrombin promptly controls bleeding from oozing surfaces, from large veins and from the dural sinuses. Muscel as a hemostatic agent is less adaptable than fibrin foam and causes considerably more tissue reaction. Fibrin foam has several advantages over soluble cellulose, though the tissue reaction to the two substances is similar. Fibrin foam has been applied at more than one operation in 34 cases without change in tissue response or other damage. The usefulness of fibrin foam is enhanced by the fact that it may be molded to the contour of the bleeding surface before or after application, that it retains that contour after pressure is released and that it adheres quickly and permanently to the bleeding surface.

Sutureless Reunion of Nerves with Elastic Cuffs of Tantalum.—Weiss describes a method by which tantalum foil can be fashioned into resilient self-sealing tubes, which may be used as cuffs for the sutureless linking of severed nerve stumps in the manner previously described for arterial sleeves. Preliminary observations on monkey and cat nerves joined by this method have demonstrated that excellent reunion between the stumps with the properties required for optimal nerve regeneration may be achieved if the sleeves have been suitably shaped and properly handled.

Cystoscopic Implantation of Radium Element in Carcinoma of Bladder.—Moore states that cases suitable for closed methods of treatment, with or without the use of radium, must be selected with care. They comprise chiefly tumors of a low degree of malignancy, and occasionally small or early tumors of grades 3 and 4. In a series of 96 cases of carcinoma of the bladder, 16 were inoperable and treatment was refused in 10. Of the 70 patients who underwent treatment, 36 were treated by closed methods and 34 were subjected to open operation. If cystoscopic implantation of radium is contemplated, the tumor should be in a location favorable for a good view and for attack through a direct cystoscope, which would include tumors involving the trigone, lateral bases, posterior wall and the posterior half of the lateral walls. If the growth is in the vesical dome, the anterior wall or anterior half of the lateral walls this method is unsuitable. Radium element should be employed cystoscopically in preference to radon seeds because the cystoscopic implantation of small platinum needles by the author's method is technically no more difficult than the implantation of radon and on expiration of the allotted time of radiation the needles

are removed. Radon usually is left in place and becomes a permanent foreign body, which may be undesirable in the presence of infection, especially in the region of the trigone; in charity services and in indigent patients in private practice the expense of gold radon seeds may be prohibitive. The author treated 11 patients by cystoscopic implantation of radium element. Of the 5 who have died the survival varied between six months and six years. Among the 6 still surviving, some have been treated quite recently. The neoplasms were mostly of grades 2 and 3. The chief indication for irradiation in bladder carcinoma has been advanced age. It is generally agreed that the avoidance of open surgery in such a group is desirable.

Sulfathiazole Prophylaxis for Gonorrhea.—Gooch and Gorby describe three different plans of sulfathiazole prophylaxis in units with venereal disease rates in excess of 100 per thousand a year. The use of regularly established prophylactic stations (these stations do not administer sulfathiazole) as soon as possible after contact was encouraged, directing that sulfathiazole should be considered as an adjunct to such measures rather than supplanting them. It was emphasized that sulfathiazole in no way protected against syphilis and that syphilis prophylactic measures should not be neglected. At the time the sulfathiazole prophylaxis was put into effect the annual gonorrhea rate of the units affected averaged 170 per thousand. After two and one-half months of application the annual rate was reduced to an average of 70 per thousand. The rate as it now stands is due to cases contracted on furloughs, which often means that the men are away from the organization for fifteen days. They frequently return from furlough with acute gonorrhea. Aside from the method in use with those units exhibiting high venereal disease rates, different methods were used to establish the most efficacious dosage, the smallest effective dose, the proper timing of the dosage and to compare sulfathiazole gonorrhea prophylaxis with the standardized venereal disease prophylactic method using soap, five minute urethral instillation of 2 per cent solution of strong protein silver and ointment of mild mercurous chloride. After describing the prophylaxis used in four different groups the author says that in those using sulfathiazole the drug was entirely administered after the exposure except in group 4. In this group 2 Gm. of sulfathiazole was given as the man left his company area on pass and when he returned, the drug being given before and after exposure. During the period covered by this report there was a reduction in the venereal disease rate from gonorrhea alone from an approximate annual figure of 16 to 11 per thousand. The authors concluded that (1) sulfathiazole is an effective gonor-

rheal prophylactic agent, (2) the average individual prefers the sulfathiazole type of prophylaxis over the urethral instillation method, (3) sulfathiazole gonorrheal prophylaxis is effective for a longer period following exposure, (4) in prophylactic dosage toxicity and sensitivity reactions to the drug are negligible, (5) a total dose of 2 Gm. of sulfathiazole appears as effective as twice that amount, (6) there was a concurrent lowering of the common respiratory disease rate in those units placed on a mandatory sulfathiazole gonorrheal prophylaxis regimen, i. e. those units with high venereal disease rates, and (7) there has been a concurrent lowering of the syphilis rate as a result of increase in the number of prophylactic administrations.

*Incidence of Peptic Ulcer. M. Patterson.—p. 570.

Ephedrine Sulfate in Nocturnal Enuresis.—Parkhurst suggested in 1930 the use of ephedrine in incontinence of urine. Kittredge and Brown used the drug for the control of enuresis in 25 children who were chronic bed wetters. Twenty-three of these immediately became continent and remained so as long as the drug was administered. It was given in a single dose of 34 grain (50 mg.) each night at bedtime, and no other measures were taken to influence the bed wetting habit. The drug was continued in each case for two weeks and then withdrawn. It was then noted that enuresis returned in 11 of the 23 children; the other 12 remained well. The 2 who were not influenced were incorrigible children of low mentality. Each case is first carefully studied to eliminate organic pathologic conditions which might cause frequency of urination stimulating enuresis. It is always necessary to eliminate the possibility of infection in the urine, mechanical obstruction to the emptying of the bladder with resultant retention, or neurologic defect which would interfere with normal function of the bladder. The drug is recommended because of its ease of administration, absence of disagreeable reactions and excellent results.

Incidence of Peptic Ulcer.—Patterson states that statistical reports from various countries reveal a manifest variability in the incidence of peptic ulcer from country to country but that

in America approximately 12 per cent of all persons have peptic ulcer at some time in their lives. The ratio of gastric to duodenal ulcer is extremely variable, but among patients seen in this country duodenal lesions predominate about 4 to 1. The period of life from the thirtieth to the sixtieth year with a peak in the middle age years (35 to 50) is the most frequent period for peptic ulcer, and duodenal ulcer makes its appearance earlier in life than the gastric ulcer. Peptic ulcer is predominantly a lesion found in the male. This predominance is more obvious in cases of duodenal ulcer than of gastric ulcer. The main evidence, though slight, points toward an endocrine basis. Hemorrhage is the most frequent complication, but perforation is the more serious. Opinions as to the role of occupation in peptic ulcer are contradictory. The impression that the disease is most prevalent among those who lead lives entailing great nervous strain and responsibility awaits proof. Draper's contention that there is a body type peculiar to peptic ulcer is unreliable. Some authors obtained a positive family history in a large percentage of ulcer patients. Peptic ulcer is of importance in the present national crisis. Dyspepsia is the number one medical problem in the armed forces, and reports show that the incidence of ulcer is 30 per cent or over, with the majority in the duodenum. The author thinks that the high incidence of peptic ulcer in the armed forces is not a result of the war but that the war called attention to the numerous cases which existed but were not recognized.

Cesarean Section: Advantages and Disadvantages of Present Day Types. J. P. Marr.—p. 1230.

Preventive Aspects of Coronary Disease.—Plotz thinks that preventive measures are possible for a certain number of patients with coronary disease or myocardial infarction. First there is the patient who has already had one attack of coronary thrombosis. Next there is the man with angina pectoris. Next there are middle aged and aged persons with electrocardiographic evidence of heart damage without symptoms. Given certain conditions, their coronary arteries will fail. Somewhat less vulnerable but still requiring special vigilance are patients with hypertension, diabetes, myxedema, polycythemia or elevated blood cholesterol from any cause. Coronary thrombosis practically never occurs in an undamaged artery. It is preceded by an atheroma. Terrifying pain, shock and changes in the cardiogram are only the final act in coronary thrombosis. Preceding this there may be a prodromal stage of precordial pain resembling coronary pain. It is like a prolonged, atypical attack of angina pectoris and is a reflection of reduced coronary circulation and anoxia of the heart. If a patient falls into one of the vulnerable categories such an attack should lead one to suspect an impending coronary thrombosis. A man who suddenly develops angina pectoris for the first time should be put in the same category. These patients should be treated as though they had a cardiac infarction. Bed rest for five to fourteen days and use of papaverine to increase the pulmonary circulation are essential. Patients should be warned against the use of glyceryl trinitrate at this stage. If it does not relieve pain promptly it should not be used again, because the repeated use lowers the blood pressure and increases the possibility of infarction. Sharp and prolonged reduction of blood pressure may be fatal to a patient of the vulnerable classes. Therefore he must be protected against such events as shocking operations, spinal anesthetics, which lower the blood pressure, and severe hemorrhages. In this connection the author cites several illustrative cases and says that for the past two years he has employed slow plasma transfusion for those patients whose systolic blood pressure has fallen below 90. He feels that several lives have been saved by preventing the coronary blood pressure from falling too low.

Poisoning with Thiocyanate in Hypertension.—Weeks reports 2 instances of severe potassium thiocyanate intoxication, one in a 41 year old married Negro woman who recovered and the other in a 45 year old white married man whose illness terminated in death. Both patients presented a clinical condition characteristic of severe thiocyanate intoxication in which psychosis, delirium, confusion and signs of central nervous system irritation predominated. The highest blood level obtained from the patient who recovered was 32 mg. per hundred cubic centimeters and in the fatal case it was 36 mg. per hundred cubic centimeters. The latter patient lapsed into coma on the third hospital day and died shortly thereafter. Thiocyanate intoxication was not suspected on admission in either case. An unusual feature of both cases, and one which has been previously reported in only 1 or 2 cases, was the occurrence of unexplained vascular phenomena. The patient who recovered had clinical, physical and x-ray evidence of pulmonary infarction. The explanation of its production was not apparent. In the other case there was found at necropsy a subdural hematoma in the left frontoparietal region which had ruptured into the subarachnoid space. There was no history of head injury before death, and no explanation was found at necropsy. Anginal pain, arterial thrombosis and painful enlargement of the thyroid may also be produced. The high cerebrospinal fluid thiocyanate level found in the 2 cases reported here suggests that signs and symptoms of severe poisoning are primarily due to the toxic effect on the central nervous system. This is substantiated by the absence of significant pathologic changes in other organs.

Filariasis.—Ramey says that filariasis is primarily the result of fibrotic changes, causing obstruction to the lymphatic and venous flow. Among the microscopic changes are hyperplasia of the connective tissue and infiltration of lymphocytes, basophilic cells and eosinophils. These changes may be manifested as (1) chronic adenitis with or without obstruction and elephantiasis or (2) dilatation of lymphatics with or without elephantiasis. Some other lesions are (1) the lymphatic varix, which is a tumor consisting of a mass of dilated lymph vessels, (2) lymph scrotum, the result of dilatation of the scrotal lymphatic system and pronounced lymphedema, elephantiasis frequently supervening and adding to the enlargement, and (3) elephantoid

fever, which is characterized by pyrexia attributable to inflammation of intra-abdominal or intrapelvic structures and is usually associated with pain. The onset of the disease is characterized by pyrexia of 102 to 104 F., headaches, rigor, anorexia, often nausea, occasionally vomiting and a depressed mental state. The affected part presents signs of an acute inflammatory process, which may be of the lymphatic type or the erysipeloid variety; usually the acute symptoms largely subside in a few days, but the pronounced swelling persists. More than 70 per cent of cases recently reported from a mobile hospital showed scrotal involvement and, in more than half of these, involvement of an extremity. Septicemia and death may supervene. The tendency of the fever to recur, the severe rigor, pyrexia and terminal diaphoresis have caused it to be mistaken for malaria. There is no specific drug therapy for filariasis. The treatment should consist of bed rest, morphine for pain, elevation of the affected part to assist in postural drainage, a semielastic bandage to prevent swelling, keeping the skin well cleansed with soap and water, sulfonamide drugs, which frequently are found to exercise a distinctly beneficial effect, and surgical operation for such conditions as lymph scrotum. The only known definite aid to filarial disease is removal to a cool climate; the patient should be told frankly the nature and prognosis of the disease. The author stresses that filariasis may be acquired after only a few weeks stay in an endemic area. The extensive distribution of American forces in areas where filariasis is endemic suggests that filarial infection may be introduced in all parts of the United States. It becomes necessary to include a consideration of filariasis in the differential diagnosis of acute fevers, edema, pseudodema, varicosities, glandular enlargements, lymphatic disease, general enlargements of the extremities, synovitis and arthritis in all persons returning from the tropics and subtropics.

Rh Factor in Intragroup Blood Transfusion Reactions.—Butler and his associates observed an Rh negative obstetric patient who carried a dead fetus for two months and who then at the middle of the seventh month of pregnancy aborted a macerated stillbirth. Following the abortion, because of uncontrollable uterine hemorrhage, the patient went into shock. One hundred cubic centimeters of group O Rh positive blood was administered. A severe hemolytic transfusion reaction occurred which was characterized by chills and fever, hemoglobinuria, jaundice, oliguria and convulsions. The blood chemical findings are tabulated. Ten days after the transfusion reaction the woman had generalized convulsions, but she gradually recovered. The authors selected 25 similar cases of intragroup transfusion reaction from the literature and present them in tabulated chart form. They also outline a rational method of therapy. They emphasize that under no circumstances should obstetric patients be transfused with Rh positive blood unless the patients have been tested for the Rh factor.

Fractures of Neck of Femur.—Siris and Ryan analyze the management of 157 consecutive fractures of the neck and intertrochanteric region of the femur seen in the fracture service of the Third (New York University) Division of Bellevue Hospital from Jan. 1, 1941 to June 30, 1943. They stress that the treatment of choice for the intracapsular fractures in the aged and feeble is the immediate insertion of a Smith-Petersen cannulated three flanged nail or similar device. The treatment of choice for the intertrochanteric fractures in the aged is the immediate insertion of a device incorporating the principle of a Smith-Petersen nail and Hawley bar, preferably a Moore-Blount blade plate. For intertrochanteric fractures in the younger age group bilateral Russell traction suspension has given satisfactory results, and the authors see no reason at present to change their opinion. External pin fixation should not replace internal fixation for fractures of the hip or intertrochanteric region. Other than expediting the procedure of transfixion and minimizing the immediate trauma, it has none of the advantages of internal fixation. It is an extremely hazardous procedure and should be restricted to those who have had experience and are familiar with its technic. The authors think that the patients who are in a poor physical condition on admission have a better chance of survival if they are operated on immediately rather than waiting to see if their general condition improves. They disagree with the selection of survivors policy in which all patients are treated conservatively for a few days and then the operation is decided on only for those who it is expected will survive. Immediate operation permits early ambulation in bed without pain and reduced incidence of potential complications and allows early ambulation with crutches. The use of local anesthesia, focal skin clips and guide wires and the three sets of indispensable roentgenograms to determine (1) the accuracy of reduction and location of the skin clip in relation to the head of the femur, (2) the position of the guide wires and (3) the position of the nail will enhance the ability of the surgeon to expedite the proper insertion of the transfixion device.

Femoral Vein Ligation in Pulmonary Embolism.—Lowenberg reports 3 cases of pulmonary embolism in which the femoral vein was ligated, with cessation of the embolic episodes. He also reports 2 cases in which ligation was not performed, with fatal consequences. Emphasizing the importance of early recognition of thrombophlebitis of the lower extremity and especially in the deep veins of the calf, he discusses the importance of Homans' test and the status of venography. He advocates femoral vein ligation as a routine emergency procedure whenever pulmonary embolism incident to lower extremity thrombophlebitis has occurred. In such instances the procedure may well be life saving. Whether femoral vein ligation is to be routinely performed in all cases of deep vein thrombosis remains to be proved, but in time the dictum may well be "the treatment of femoral vein thrombophlebitis is femoral ligation." Ligation of the femoral vein at as high a level as possible often has a salutary effect on the thrombophlebitic process even though the ligation is not performed entirely above the inflammatory process, owing to total interruption of the blood flow through the affected veins.

Medical Treatment of Pulmonary Embolism.—Beckwith shows that the classic picture of pulmonary embolism is not difficult to recognize. When a patient who has been lying in bed sits up or strains at stool and suddenly becomes dyspneic and develops severe substernal pain, pallor, sweating, weak rapid pulse and low blood pressure, the diagnosis is obvious. At times the symptomatology may be bizarre. Pneumonia, pleurisy or progressive heart failure may be suspected. The finding of a hitherto unsuspected thrombosis of a deep leg vein may be a lead. X-ray examination may also be helpful. Characteristic electrocardiographic changes often occur. Careful clinical examination of the patient is very necessary, and detection of signs indicating pulmonary hypertension and right ventricular failure is important. When an acute episode occurs and the diagnosis of pulmonary embolism is made, therapy should be immediately instituted. This should be directed at relieving the anoxemia by the administration of oxygen in high concentration and simultaneously making an effort to reestablish the impaired circulation. The latter can be done by the administration of atropine $\frac{1}{50}$ grain (0.0013 Gm.) and papaverine $\frac{1}{2}$ grain (0.032 Gm.) intravenously. Then atropine and papaverine should be given every four hours. The response is often dramatic, and a patient who looks moribund may be "responsive" in a short while. The heart rate becomes slower, blood pressure rises, the heart sounds become louder and the color improves. During the past two years the author has seen 3 cases of pulmonary embolism shortly after the condition occurred. All were treated as described and all obtained dramatic relief following the initial attack. Two died later with subsequent attacks and 1 recovered completely. It is probable that, had the focus of the embolus been found, the latter episodes could have been prevented. The cases are presented.

Erythroblastosis Foetalis. J. R. Gilmore.—p. 1.

*Scheme for Prevention of Cross Infection in Children's Wards. N. M. Jacoby.—p. 26.

Prevention of Cross Infection in Children's Wards.—Jacoby describes a scheme which was to guard against the dangers of cross infection and was carried out for a year in a new children's ward. A plan of the ward is shown in a diagram. Infants up to 18 months of age who had no infection were admitted to single rooms where no case of known or suspected infection was ever allowed. Infants up to 18 months of age who, although suffering from an infection which excluded them from class 1, are themselves equally susceptible to cross infection, were likewise admitted to single rooms. Children over the age of 18 months suffering from noninfectious disease, e. g. rheumatic fever, chorea, nephritis, diabetes and epilepsy, were admitted to the larger wardlets (with 4 to 6 beds). Children of all ages suffering from infectious diseases, e. g. tonsillitis, respiratory infection, alimentary infection and otitis media, were admitted to the small wardlets, one type of disease being kept in each wardlets as far as possible. Children of all ages suffering from tuberculosis were admitted to the large ward originally designed as a solarium. Only fully trained nurses or senior probationers were selected for nursing, and as far as possible no nurse was given charge of "clean" and infected cases at the same time. All doctors, nurses, students, cleaners, visitors and any one else who wished to enter a ward was required to wear a gauze mask covering the nose and mouth. Infectious cases were nursed on full barrier precautions. Children who were not continuously in bed were not allowed to leave their rooms. The infants' feeds were prepared with full aseptic technic. No precautions, other than those in general use in the hospital, were taken over the food of the older children. Visitors were discouraged. The best results as regards prevention of cross infection were obtained in groups 1 and 2, who were given the best bed isolation. The highest incidence of cross infection was among the tuberculous children, and this is readily explained by the fact that they occupied the largest ward and stayed in the hospital for very long periods. The total incidence at 6 per cent appears to be of a low order compared with 18.9 per cent reported by Wright in 1940. In the conclusion the author stresses once more the importance of bed isolation, careful classification on admission, a competent nursing staff and face masking. He shows that, if children's wards are to be made safer, attention will have to be paid to their architecture, and the staffing with nurses must be on a generous scale. Moreover, the number of beds for children will have to be increased.

Unusual Electrocardiogram in Dextrocardia. J. M. Holford.—p. 105.

Auriculoventricular Rhythm. R. A. Miller.—p. 107.

Complete Heart Block.—Campbell discusses 64 cases of heart block, mostly complete, which were seen during the same period as 29 cases with dropped beats and 140 cases with latent heart block. Of the patients attending the cardiographic department of Guy's Hospital during twelve years 0.6 per cent had complete, 0.5 per cent partial and 2.2 per cent latent heart block. The author gives particular attention to the prognosis, incidence and significance of Stokes-Adams attacks and the extent to which complete block remains persistent or varies to lower grades of partial or latent block. Complete heart block is most

often seen in men in the seventh decade with enlarged hearts and atherosclerosis but no other evidence of gross heart disease. Four fifths of the patients were men and 84 per cent were over 50 years of age. Syphilitic and rheumatic heart disease were responsible for only just over 10 per cent of the cases. Myocardial disease was responsible in three fourths of the cases. Cardiac enlargement with no other signs of atherosclerosis was the evidence of myocardial disease in nearly half of the cases, high blood pressure, angina pectoris or congestive failure being present in the other half. The heart rate averaged just under 35 (excluding congenital cases, in which it was generally 40 to 56). Heart block may be complete, partial, partial with dropped beats or latent. Complete heart block may be established or varying, changing to other degrees of block, or interrupted. It may also be transient, due to a known infection or to a specific episode such as cardiac infarction, or paroxysmal, of which there are two varieties, paroxysmal complete heart block when the usual rhythm is latent heart block and paroxysmal heart block (complete) when the usual rhythm shows a normal PR interval. Although complete heart block is a serious lesion, some, especially those under 40, live for many years in reasonably good health. Of the author's patients 50 were followed for more than two years or until death. Thirty-four were dead after an average period of 2.5 years; others were observed for from two to six years and still others for from seven to twenty years. Stokes-Adams attacks were present in half the patients with complete heart block. When they were present they were one of the earliest if not the first significant symptom of heart block. In those without Stokes-Adams attacks, dyspnea or attacks of faintness or dizziness were the main presenting symptoms. The prognosis was considerably worse in those with Stokes-Adams attacks. Of 30 with Stokes-Adams attacks 24 died during the period of observation, whereas of 20 without Stokes-Adams attacks only 10 died. Sixty-one per cent of those with Stokes-Adams attacks died suddenly and of the others only 1 died suddenly. If when a patient is first seen with complete heart block he has not had a Stokes-Adams attack, the risk of such an attack developing or of his dying suddenly is not great, and with each month that has passed the risk becomes still less.

16:1-34 (March) 1944

*Treatment of Arterial Hypertension with Potassium Thiocyanate. J. L. D'Silva and G. Evans.—p. 1.

Potassium Thiocyanate in Arterial Hypertension.—D'Silva and Evans studied the effects of potassium thiocyanate in the treatment of 25 patients with hypertension. During the first week the patients were given three times daily 0.1 Gm. of potassium thiocyanate. At the end of the week, that is, after 2.1 Gm. had been given, the serum thiocyanate content was determined. In some patients the serum concentration was less than 4 mg. per hundred cubic centimeters, in others it was between 4 and 11 and in still others it was over 11, in 1 patient as high as 15. This showed that the requirements of the patients varied greatly and that caution was necessary. The dosage was altered in steps of 0.4 Gm. weekly until a serum level of from 5 to 12 (usually from 7 to 9) mg. per hundred cubic centimeters was obtained. Once the individual patient's requirement of potassium thiocyanate was established in the hospital, the follow-up after discharge from the hospital, with blood thiocyanate estimations at less frequent intervals, was fairly satisfactory. Summarizing their observations, the authors say that 11 of the 25 patients responded by a considerable fall and 6 by a slight fall in blood pressure. In 8 cases the blood pressure was unchanged. Headache, vertigo and lack of concentration were the associated symptoms most often relieved. The drug was administered safely to elderly patients and those with electrocardiographic evidence of myocardial degeneration. Two patients with cerebral arteriosclerosis benefited greatly by treatment. No patient with severe renal dysfunction was encountered in this series. Two patients were poisoned with the drug but made uneventful recoveries when its administration was suspended.

Carcinoma of Fallopian Tube. R. M. Corbet.—p. 196.

Heart in Pregnancy.—Donovan points out that the effects of pregnancy on the normal woman may produce both symptoms and signs which closely simulate heart disease, e. g. shortness of breath, palpitation, fulness of the neck veins, rales at the lung bases and a change in the radiographic silhouette of the heart similar to that of mitral stenosis. Citing figures mostly of American investigators, Donovan shows that heart disease is not a common complication of pregnancy. He cites a New York report which indicates that in mothers with known heart disease the death rate was 10.3 per thousand pregnancies, compared with 2.0 per thousand for all obstetric patients. Post-mortem studies by Glasgow authors revealed that of 813 patients who succumbed during pregnancy or puerperium 108 had acute or chronic heart lesions. Mitral stenosis is the predominant lesion in heart disease complicated by pregnancy. Auricular fibrillation causes approximately four times more deaths than any of the others. Antepartum supervision, with early hospitalization in those cases needing it, materially reduces the mortality rate. There are two schools of thought regarding the best methods of delivery. One favors cesarean section; the other prefers delivery by the natural route with general anesthesia and the application of forceps at a certain stage. Those who prefer cesarean section argue that it is possible to choose a time for the operation with a strict regard for the heart condition of the patient; physical strain of labor is avoided, and *there is reasonable certainty of producing a living child.* Those who favor natural delivery maintain that women with heart disease usually have easy labors, owing possibly to the laxity of the tissues. The sudden flooding of the circulation at the time of the contraction of the uterus may be a causal factor in the increased incidence of heart failure in the first twenty-four hours of the puerperium. Venous section and the application of a tight abdominal binder as soon as the uterus is evacuated may help. The danger involved in anesthetizing and operating on pregnant women suffering from heart disease has been exaggerated. Probably nitrous oxide and oxygen supplemented by ether is as good as any anesthetic. The use of spinal anesthesia is of doubtful wisdom. It is inadvisable for patients who suffer or have suffered from heart failure to become pregnant. Antepartum clinics should have facilities for special investigations; x-rays and electrocardiographs should be available. Some antepartum cases require hospital treatment, investigation or supervision.

Pneumococcal Meningitis Treated with Penicillin.—Cairns and his co-workers report 8 cases of pneumococcal meningitis treated with intrathecal penicillin, supplemented in 3 cases with penicillin intramuscularly. In 6 cases recovery was complete;—in 2 cases leptomeningitis was controlled but death subsequently occurred, one from subdural abscess, the other from brain abscess, ventriculitis and obstruction of the

aqueduct of Sylvius. Both sodium and calcium salts have been used intrathecally. Concentrated solutions of approximately 5,000 units per cubic centimeter were made in distilled water, which after Seitz filtration and assay were diluted in water or isotonic solution of sodium chloride to 250 to 500 units per cubic centimeter. Repeated daily injections of these solutions into the lateral ventricles or lumbar subarachnoid space in amounts of 4 to 10 cc. have not produced impairment of nervous function. The usual dosage was 3,000 to 4,000 units per injection. This was given daily for from four to nine days in the uncomplicated cases. The dose was varied: the smallest, 659 units, caused only temporary disappearance of pneumococci; the largest, 20,000 units, was too high for this preparation and produced a severe reaction. The total amount injected intrathecally has varied between 10,000 and 85,000 units. In the mild cases the intrathecal injections of penicillin can all be given by the lumbar route, but the ventricular route should be employed if there is not prompt clinical improvement or if blockage of the cerebrospinal pathways is suspected. In severe cases it would seem desirable to combine lumbar and ventricular injection. When adequate supplies of penicillin become available it may be wise to give penicillin intramuscularly or intravenously for a few days. The authors treated 8 further cases, in 2 of which death occurred. This makes a total of 16 fully treated cases, with 12 recoveries. The majority of the recent cases provided additional evidence of the beneficial effect of sulfonamides. Although much less effective than penicillin sulfonamides can be administered by mouth, and they pass readily from the blood stream into the cerebrospinal fluid.

Endocrine Obesity and Spastic Abdominal Syndrome.

—The subjects of Schmidt's report were 3 women, 29, 44 and 46 years of age with endocrine adiposis associated with a predominant spastic abdominal syndrome. Froehlich's type of hypophysial-genital adiposis was present in 1 case and hypophysial-adrenal obesity associated with pronounced virilism in the 2 others. The spastic abdominal syndrome corresponded to the picture of spastic neuropathic colitis. Renal and ureteral colics in addition to intestinal colics were predominant. They are considered to be manifestations of the same functional dis-

order in two closely related organic systems rather than disorders which are different in principle. Anatomic changes could not be demonstrated in the intestinal canal, but mild bilateral hydronephrosis was shown by 2 of the cases. This hydronephrosis may have been a sequel of the ureteral colics rather than their origin, since a mechanical cause was missing and hydronephrotic changes could not be demonstrated on roentgenologic and postmortem examination. Primary functional disturbances of intestine and ureter in the sense of neuromuscular dyskinesia on a vegetative-nervous base are suggested. Psychic anomaly was present in all 3 cases. A basic depressive attitude was manifested and was associated with a pronounced hysteriform tendency. The accompanying polyneurotic syndrome was characterized by subjective complaints without any objective neurologic findings. The porphyria examination always was negative. The conformity of the symptom complex of these 3 cases suggests an internal genetic relationship, but no indication was presented with regard to its type.

Renal Diabetes in Infant: Case. D. Duran.—p. 335.
Vitamin B₁ in Therapy of Whooping Cough. L. Cortés de los Reyes.—p. 347.

Early Rising and Pulmonary Embolism.—Marescot emphasizes the importance of early rising after abdominal operations in prevention of pulmonary embolism. The author performed 1,192 abdominal operations during a period of five years in the Pontevedra Hospital. Early rising was practiced in the majority of the cases. Of the small group of patients who remained in bed for more than one week after the operation thrombophlebitis occurred in 4. The patients were ordered to rise immediately from bed, to move their legs and to walk. Phlebitis was controlled. Pulmonary embolism occurred in 1 case. It was benign and controllable.

*Dissecting Aneurysm of Aorta with Diagnosis During Life of Patient. J. E. Israel and J. Valotta.—p. 174.
*Adrenal Cortex Extract in Vomiting of Pregnancy. E. Bottioli.—p. 181.

Dissecting Aneurysm of Aorta.—According to Israel and Valotta, diagnosis of dissecting aneurysm of the aorta during the patient's life is difficult. Changes in the tunica media of the artery constitute the main pathogenic factor. Fissure of the intima layer of the artery and arterial hypertension are inconstant secondary factors. Sudden acute precordial pain which radiates to the back and to the lumbosacral region along the course of the aorta, combined with the feeling of impending death, followed by shock, paralysis and signs of arterial obstruction are the predominant symptoms. X-ray examination shows great enlargement of the thoracic segment of the aortic shadow, double border of the aortic shadow in the frontal view and left ventricular hypertrophy. Recovery after the acute attack is extremely rare, although possible. The authors report that a man aged 43 with hypertension of long standing suffered an acute attack of severe precordial pain followed by paralysis of both legs. The roentgenogram was typical of a dissecting aneurysm of the aorta. Treatment consisted of intravenous injections of papaverine and bed rest. Paralysis greatly improved, the patient being able to walk one month after the attack. He led a comfortable existence for eight months, when he suddenly died. A necropsy was not permitted.

Adrenal Cortex Extract in Vomiting of Pregnancy.—Bottioli administered adrenal cortex extract to a large number of patients during the last three years for vomiting of pregnancy. The patients belonged to four groups: (1) those with nausea but no vomiting, acidosis or asthenia, (2) patients with acute nausea, vomiting and asthenia but without acidosis, (3) patients with acute nausea, vomiting, asthenia and acidosis and (4) patients with intractable vomiting. Intravenous injections of dextrose solution, a diet of thirst and hunger, enemas of urine of pregnant women, large doses of sodium bicarbonate,

insulin, belladonna and thyroid preparations failed in all of the cases. Intramuscular injections of desoxycorticosterone and adrenal cortex extract controlled the nausea and vomiting within three days or a week. It is advisable to administer tablets of 0.10 Gm. of powder of the cortex for one week after vomiting has been controlled. Adrenal cortex extract is a harmless substance which has no contraindications.

Constrictive Pericarditis and Its Therapy.—The concept of cardiac insufficiency resulting from embarrassment of the diastolic phase of the heart action will be of considerable help in the diagnosis of constrictive pericarditis and as an indication for surgical intervention. Differentiation between tuberculous and rheumatic nature of the condition is of no importance, so far as intervention is concerned, except where definite tuberculous changes in other organs are present, when the operation should not be performed. The earlier the intervention is performed, the more promising the result. Operation gives best results where a complete cure from acute pericarditis has occurred. In such cases even the removal of the feltlike fibrous tissue over the auricles and between the large vessels may be possible and the formation of adhesions with proliferation of connective tissue and cicatrization may be prevented. Operation is recommended nevertheless for the very grave cases, since they are not amenable to any other type of treatment. It is important to commence the surgical intervention on the left ventricle in order that an increased cardiac output may be coped with. Definite improvement may result from this conduct of the operation when first the left ventricle and the right ventricle and even portions of the auricles are freed. Unsatisfactory results, in spite of the fact that the heart had been freed to a large extent, may be due to the anatomic conditions of the posterior wall of the pericardium and its junction with numerous vessels. Adhesions may be particularly pronounced at this area. Two conditions throw light on this state before the intervention. Pulmonary stasis at the base of the lungs, as demonstrated on roentgenologic examination and not amenable to conservative treatment of the heart, is to be regarded as a sequel to the massive obstruction to the filling power of the left auricle. The electrocardiographic recordings of 7 of 20 patients with definite constrictive pericarditis revealed auricular fibrillation, and a peculiar change of the P deflection was shown by the electrocardiograms of the other 13 patients. It was interpreted as a transitional change from the normal stimulation period to fibrillation and as an impairment of the auricular contraction. That corresponds with the anatomic condition of some of these cases, in which calcification was demonstrated on roentgenologic examination. The electrocardiogram of 13 of the 20 cases also showed a definite change in the ST segment, which was depressed more or less below the zero line, particularly in leads 2 and 3. There was an upward convexity of the ST segment ending with a negative T. The peculiar change of the P deflection associated with the well defined changes of the ST segment strongly suggests the occurrence of constrictive pericarditis. In these cases the success of surgical intervention is doubtful and a two stage operation is suggested in those in which the parietal layer and the visceral pericardium can be separated. Conservative management with digitalis, rest, diet and systematic training of the functional capacity of the heart is advisable during the period of improvement following the first stage operation. The second operation is easier and will make more promising the freeing of the right ventricle and of the auricles.

Book Notices

Heart Disease: An Elementary Reference for Physicians. By Robert S. Berghoff, M.D., F.A.C.P., Clinical Professor of Medicine, Loyola University School of Medicine, Chicago. Issued Under the Auspices of the Post-Graduate Committee of the Illinois State Medical Society. State of Illinois, Department of Public Health, Circular No. 176. Paper. Pp. 63. Springfield, 1944.

This booklet has been prepared as an elementary syllabus on heart disease for physicians. There are nine chapters of from three to fourteen pages, on congenital heart disease, rheumatic endocarditis, syphilitic heart disease, arteriosclerotic heart disease, acute and subacute bacterial endocarditis, hypertensive and thyroid heart disease, diseases of the pericardium, abnormalities of rate and rhythm and left ventricular failure vs. right ventricular failure. The plan is excellent but the execution is disappointing. The book fails to present the newest advances in our knowledge of various conditions, such as congenital heart disease in the case of the auricular septal defect. In the discussion of rheumatic heart disease there is little or no statement of the myocardial involvement which is predominant in the early cases and which is responsible for the early dilatation and murmurs. Valvular deformity is a later manifestation. Syphilitic heart disease is essentially syphilitic aortitis and in many cases does not show heart involvement at all. "Heart involvement" should really be "aortic involvement." It is impossible to diagnose syphilitic aortitis early in its course. The symptoms and signs described are late, and it should be emphasized that percussion is notoriously inaccurate in the measurement of the aorta.

Under the heading arteriosclerotic heart disease many cardiologists would doubt any common existence of the senile heart per se, in persons in the fifties, for example. Also individuals vary much in their aging. It is important to recognize that coronary disease is not necessarily a disease of senility; it increases with age, of course, but it is an important disease of youth. Angina pectoris is not necessarily severe. Its position, character and causation are much more important than its severity. Minor myocardial infarction does not require eight weeks for adequate cicatrization, at least for consideration in treatment clinically. Four to six weeks suffice for adequate scar formation. Also it is important to note that the status anginosus, as in the case of acute myocardial infarction and angina pectoris decubitus, is not a chronic state. It should be regarded as an acute or subacute type of heart disease.

In the discussion of subacute bacterial endocarditis, some mention should be made of the reduction of mortality that has already occurred by the use of the sulfonamides and penicillin. In the discussion of hypertensive and thyroid heart disease pulsus alternans is inserted after gallop rhythm as a synonym, but these two conditions are not synonymous. Also most doctors would consider tobacco contraindicated in hypertension, since it is known that most persons show an elevation of blood pressure, especially if they are already hypertensive, during and immediately after smoking. In the chapter on diseases of the pericardium, the important condition of chronic constrictive pericarditis has been omitted. In chapter 8 digitalis intoxication as an important cause of paroxysmal ventricular tachycardia should be included. In the final chapter on congestive failure, one cannot separate, so clearly as is done here, either the symptoms or the treatment of left and right ventricular failure. Cyanosis due to pulmonary congestion is the result of left ventricular failure, not of right, but there may be added cyanosis in right ventricular failure due to stasis in the peripheral circulation. Pain of aortic origin or otherwise is not a characteristic symptom of left ventricular failure, and clubbed fingers are not characteristic of right ventricular failure. Finally, diuretics are important in the treatment of left ventricular failure as well as of right as is also a decreased fluid intake, and it should be noted that digitalis often helps left ventricular failure strikingly.

The usefulness of this pamphlet would be greatly increased with revision to bring it up to date. There are quite a few simple typographic errors that need correction.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1943, With the Comments That Have Appeared in the Journal. Reprinted from *The Journal of the American Medical Association*. Cloth. Price, \$1. Pp. 130. Chicago: American Medical Association, 1944.

In the introduction to its "Official Rules," which have been used as a model by subsequent similar organizations, the Council on Pharmacy and Chemistry states that these were adopted "primarily with the object of protecting the medical profession and the public against fraud, undesirable secrecy and objectionable advertising in connection with proprietary medicinal articles." Later it is stated that the function of the Council is also "to advise the medical profession concerning the status of medicinal articles, . . . to publish reports on claimed advances in the use of drugs and to elaborate standards for the control and identity of drugs that are introduced into materia medica." In its earlier years the Council was chiefly occupied with examining individual preparations for compliance with the Rules, and the early reprints of the Council's reports are predominantly statements concerning the nonacceptability of many preparations. Latterly the emphasis has significantly changed to the more educational phase of the Council's work. The present volume of reprints is an excellent example of this trend. It contains only eight reports on rejected articles; and it is noteworthy that objections to these are on a much higher plane than those it was necessary to urge against the flagrantly quackish preparations of earlier days.

Perhaps the most noteworthy of the nineteen educational reports in this volume is the one declaring the Council's intention of using henceforth only the metric or centimeter-gram-second system in its publications. The report itself gives some interesting and readable history on the subject of weights and measures. Of most timely interest to the general physician as well as to the endocrine specialist is the report on nomenclature of endocrine preparations. The report gives a currently quite complete list of the available commercial preparations, including those not accepted by the Council as well as those which stand accepted. Another report in the field of endocrinology is that recognizing the use of estrogens in the treatment of prostatic carcinoma.

Attention should be called to at least two of the reports concerned with vitamin preparations, namely the status report giving the Council's decision that the evidence does not yet warrant the acceptance of cod liver oil preparations for external use and the report announcing the Council's recognition of the use of massive doses of vitamin D in the treatment of refractory rickets. The Council has previously objected to the use of massive doses of vitamin D in arthritis and in this volume includes a current comment from *THE JOURNAL* titled "Hope (false) for the Victims of Arthritis," which reemphasizes this objection.

The status report on xanthine compounds gives a much needed delimitation of the therapeutic claims that may be recognized for aminophylline and its related xanthine derivatives. Of similar interest is the report on the local use of sulfonamides in dermatology, and in the same category may be mentioned the report on agents for the treatment of trichomonas vaginitis, which points out that the present aim should not be for new medicaments in this field but for further information, especially concerning failures with those that have been used. In another status report the Council sets forth its conclusion that present evidence does not justify claims for advantage of oral use of sodium sulfonamides over the free drug.

In line with its decision to consider for acceptance various contraceptive preparations, the Council published a status report on conception control, which is included in this volume. The report comprises a series of concise statements on the various preparations and methods of control, prepared by Dr. Robert Latou Dickinson, together with a statement of criteria by which the Council will consider the acceptability of contraceptive jellies, creams and syringe applicators and nozzles, diaphragms and caps.

It cannot be too often said that this volume, as well as the other publications of the Council, remains of paramount interest to all who are concerned with rational use of therapeutic agents.

Taken all together, the printed record of the Council's work represents a fitting monument to a service born of unselfish altruism and continued in a spirit of finest devotion to the best interests of the medical profession and the public.

The Diet Therapy of Disease: A Handbook of Practical Nutrition. By Louis Peltner, M.D., Assistant Attending Physician, Long Island College Hospital, Greenpoint Hospital, and Brooklyn Cancer Institute. Cloth. Price, \$3.75. Pp. 143, with 6 illustrations. New York: Personal Diet Service, 1944.

This book is intended for the guidance of the physician in providing the greatest possible benefits to the patient from use of properly selected diets. In many cases there is no therapeutic effect to be derived from the most careful selection of food types, but in such cases proper selection at least can be of value in lightening the burdens of the body.

In the brief introductory discussion covering the basic facts of nutrition, new developments of practical significance in this field are touched on. A question might be raised concerning the classification of vitamins given here as Council accepted and not accepted. A clearer understanding of their status would probably result from their differentiation as those whose significance in human nutrition is now established and those whose relationship to human nutrition is not yet determined.

The body of the book consists of diet lists for some thirty disease conditions in their various forms as well as many types of special diets. For each a sample diet covering the meals of one day is accompanied by a helpful discussion of the fundamental pathology of the disease and the principles governing a diet for that condition. In some cases it is felt that the author attempts to cover too much ground for a book of this nature by going into the differential diagnosis of the disease state. The dietary principles set forth are based on sound, up to date scientific information with numerous references quoted. The actual diet lists are quite simple and apparently have proved themselves practical from long experience. As brought together in one book such as this, a ready reference and sample diet source is available to the medical practitioner for the application of the developments in the science of nutrition.

Fundamentals of Psychiatry. By Edward A. Strecker, M.D., Sc.D., F.A.C.P., Professor of Psychiatry and Chairman of the Department, Undergraduate School of Medicine, University of Pennsylvania, Philadelphia. Second edition. Cloth. Price, \$3. Pp. 219, with 15 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1944.

This book was first published in October 1942. Additional material was added in March 1943, and the present edition includes a single six page chapter on war neuroses that was not in the reprinting of the first edition. Otherwise the book appears to be unchanged except for minor typographic errors. The addition of this brief chapter would hardly seem to justify, in the opinion of the reviewer, a second edition. The book itself is excellent, as was pointed out in a review when it was first issued. Written by one of the leading psychiatrists in America, it is a brief, sound, compressed work, highly readable and excellent for the general medical adviser, who so often is faced with the problems of mental disease. This small manual can again be highly recommended as a useful and accurate summary of present day psychiatry.

Cancer: A Study for Laymen. Prepared for the Women's Field Army of the American Society for the Control of Cancer, Inc. [Compiled by] Clarence C. Little, Sc.D., Managing Director. Paper. Gratts. Pp. 122, with 54 illustrations. New York & Toronto: Farrar & Rinehart, Inc., 1944.

This can be regarded as an excellent manual if one keeps in mind that it is designed for the use of interested lay persons who have time to devote to study and to work in the cause of cancer control. It should not, however, be used outside the circles of interested workers. Its greatest usefulness will be among those who have at least a rudimentary knowledge of biologic science. It is prepared for the Women's Field Army of the American Society for the Control of Cancer, Inc., and is distributed free by that society, which may be addressed at 350 Madison Avenue, New York 17.

Dur American Babies: The Art of Baby Care. By Dorothy V. Whipple, M.D. Introduction by C. Anderson Aldrich, M.D. Cloth. Price, \$2.50. Pp. 367, with illustrations. New York: M. Barrows and Company, Inc., 1944.

This book is well organized and the material is completely integrated, from antepartum management through the first two years of life. The information given is what every young mother desires and is especially adapted for those who are working. There is a certain authority which comes only from one who has both practical as well as the scientific knowledge of the many problems one encounters in the care of infants. The information on most subjects is very adequate. The chapter on the development of habits and their treatment is delightfully covered and would save much valuable time of the pediatrician if all mothers could read it. The book would make a valuable reference for all persons interested in the care of infants.

One Hundred Years of American Psychiatry. J. K. Hall, M.D., General Editor, Gregory Zilboorg, M.D., Associate Editor, and Henry Alden Bunker, M.D., Assistant Editor. Cloth. Price, \$6. Pp. 649, with illustrations. New York: Published for the American Psychiatric Association by Columbia University Press; London: Oxford University Press, 1944.

Psychiatry, like other branches of medicine, has made enormous progress in the last century. In this field American psychiatrists have played an increasingly important part. This volume is not intended to list past achievements or to present a symposium on what American psychiatry is doing today but rather, as pointed out in the foreword, is intended as a historical synthesis of a century of American psychiatric evolution. It is a little surprising to find such extremely wide margins and other wasted space in a book published in these days of paper shortage. The editorial board and the contributors have been well chosen and deserve congratulations on the interesting chapters presented.

Summary of State Legislation Requiring Premarital and Prenatal Examinations for Venereal Diseases. By Aneta E. Bowden, M.A., Ph.D., and George Gould, M.A., LL.B., Assistant Director, Division of Legal and Protective Services, American Social Hygiene Association, New York. Published and distributed by the American Social Hygiene Association in cooperation with United States Public Health Service. Second edition revised by George Gould. Paper. Price, 25 cents. Pp. 30, with 2 illustrations. New York, 1944.

As of Jan. 1, 1944 thirty states had passed legislation to prevent the spread of venereal disease through marriage by requiring a premarital examination as a condition to the issuance of a marriage license. A similar number of states had enacted antepartum examination laws to prevent syphilis in the unborn child. This summary represents an adequate, dependable analysis of such laws which will serve as a practical guide to health authorities, officials issuing marriage licenses, physicians and all others concerned. It will be particularly valuable to those who may be interested in the promotion of similar legislation in states in which laws of this character do not yet exist.

The Management of Neurosyphilis. By Bernhard Dattner, M.D., Jr.D., Associate Clinical Professor of Neurology, New York University Medical College. With the collaboration of Evan W. Thomas, M.D., Assistant Professor of Medicine and Assistant Professor of Dermatology and Syphilology, New York University Medical College, and Gertrude Wexler, M.D., Instructor in Dermatology and Syphilology, New York University Medical College. Foreword by Joseph Earle Moore, M.D., Associate Professor of Medicine and Adjunct Professor of Public Health Administration, Johns Hopkins University, Baltimore. Cloth. Price, \$5.50. Pp. 398, with 7 illustrations. New York: Grune & Stratton, 1944.

This book is a practical and much needed contribution. The author published another book on modern treatment of neurosyphilis eleven years ago when he practiced in Vienna. This publication is written along the same lines. It is divided into two parts, namely technics of withdrawal and examination of spinal fluid and methods of treatment, and application and results. The part on the spinal fluid is extremely well written, concise and encyclopedic in nature. It is the best the reviewer has ever seen on the subject. The second part is a textbook in itself. Every known form of treatment is described with technic and results. This book must be purchased by any medical man who treats any form of syphilis. It is the best at the present time. There is an index of authors and subjects.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EVACUATION OF STOMACH OF INFANTS

To the Editor:—Can you suggest a dependable, safe and quick acting emetic to be used for young infants; one that may be given by mouth or by needle or both? It often happens that children get poisoned on fuel oil and the like, and emptying the stomach with a stomach tube is not altogether satisfactory because of food blocking the outlet of the tube. Syrup of ipecac, I have found, is too slow and cannot be relied on for prompt results.

C. C. Horton, M.D., Pendleton, S. C.

ANSWER.—Emetics are not as commonly used as in former times, though the list of these remedies has remained for the most part unchanged through the years. The emetics which are in common use may be briefly enumerated: Ipecac is used in the form of powder, 1 teaspoon to a glass of water or 1 tablespoon of the syrup in water repeated every fifteen minutes until vomiting is produced. Ipecac is uncertain and in large doses acts as a depressant. Zinc sulfate and copper sulfate are no longer in common use. One-half teaspoon of the zinc salt in water will usually cause emesis. Copper sulfate in 5 grain (0.32 Gm.) doses in warm water repeated in fifteen minutes will cause vomiting with only slight constitutional symptoms, but if not promptly ejected it may cause corrosion of the mucous surfaces. Mustard is safe but not certain in the desired action. One teaspoon in a cup of warm water should be given, repeated every fifteen minutes until vomiting is produced. Salt water, 2 tablespoons to a glass of water, sometimes produces the desired result. Apomorphine is a rapidly acting emetic, though most physicians are reluctant to use it for young infants on account of its toxic and depressant action. For young infants the dose is $\frac{3}{60}$ grain (0.0011 Gm.) hypodermically or $\frac{1}{42}$ to $\frac{1}{50}$ grain (0.0054 to 0.0032 Gm.) by mouth.

The emetics may be employed if lavage is contraindicated or inadvisable, though as a rule they are less reliable and are likely to be more depressing. Lavage is the method of choice in removing poisonous substances from the stomach. A catheter will serve the purpose, the diameter of which should vary with the size of the child. A small funnel may be attached to the lumen of the tube, and the stomach washing may proceed in the usual manner. In most cases it is preferable to attach a 20 cc. glass syringe (larger size if available) to the catheter. Water should be slowly and gently forced through the catheter into the stomach, followed by immediate aspiration. This washing and aspirating process should be frequently repeated until the wash water is clear and free from ingested poison. By use of the syringe the catheter is less likely to be blocked by food substances. If the poison has caused erosion of the mouth, pharynx or digestive tract the passage of a tube is contraindicated. In washing the stomach great care should be taken that food particles and poisonous substances are not aspirated from the pharynx into the lungs. It has been suggested that this accident may occur when the stomach is evacuated in kerosene poisoning, causing pneumonia; others think that if the oil remains long in the stomach it may be absorbed and partially eliminated through the respiratory organs, causing irritation and inflammation in these areas.

CONTRACTURE OF HAND AND MERCURIC CYANIDE DRESSING

To the Editor:—Can a solution of mercuric cyanide used as a wet dressing on an aluminum metacarpal splint cause a permanent deformity of the hand? I have a case in which mercuric cyanide was used as a wet dressing on an aluminum metacarpal splint for an infected hand. Later (within a few weeks) contracture of the hand developed, and now the patient is unable to close his hand completely. He was told by another physician that the cyanide solution caused the deformity. I should like to know if it is possible for the mercuric cyanide to react with the aluminum and produce the contracture of the hand that is now present.

M.D., North Carolina.

ANSWER.—There is no definite information which would permit an answer to this question. It seems extremely doubtful that a combination of mercuric cyanide as a wet dressing with an aluminum splint could be responsible for the injury. Why one should use a destructive chemical like mercuric cyanide in the treatment of a hand infection is difficult to determine.

STRYCHNINE SULFATE FOR NERVOUS MANIFESTATIONS OF ALCOHOLISM

To the Editor:—A colleague recently expressed himself in favor of strychnine sulfate for cases of delirium tremens and acute alcoholic delirium. The thesis of antagonism (chemical or physiologic) between alcohol and strychnine seems to me particularly untenable as a basis for therapy since a patient with delirium tremens may not be saturated with alcohol at the time.

A. Valdes Dopena, M.D., Havana, Cuba.

ANSWER.—A recent article (Perisson, J.: *Alcoolisme: Traitement des Complications Nerveuses par la Strychnine, Union méd du Canada* 72:317 [March] 1943) which discusses the treatment of the nervous manifestations of alcohol addiction by means of strychnine contains some startling statements: Huge doses of strychnine are given subcutaneously, the daily total used in the treatment of delirium tremens being as much as 50 mg. and the individual doses being as high as 10 mg. ($\frac{3}{8}$ grain). After two or three days the dosage may be reduced, but the treatment usually lasts from five to six weeks. Smaller doses of strychnine are used in chronic alcoholism, but about six weeks of treatment are again required. It is asserted that this treatment generally causes no untoward complications, since the alcoholic patient has a remarkable tolerance for strychnine, and that strychnine is an antidote for alcohol because it causes a functional antagonism to alcohol on the nervous centers. The article indicates, however, that strychnine has no effect in the case of a demented chronic alcoholic addict.

The rationale for this form of treatment may be questioned, since a person under the influence of alcohol will oxidize or eliminate all of his imbibed alcohol within twenty-four hours after stopping drinking. It is then no longer a question of combating the narcotic action of alcohol by strychnine. Actually there is usually a period of heightened nervous irritability following alcoholic excesses, which condition would be further aggravated by strychnine. It would be better even to give more alcohol! If the strychnine treatment should measure up to the claims made in the article cited, the good results might be due to the punitive regimen.

VITAMIN K AND PHLEBITIS IN LATE PREGNANCY

To the Editor:—A patient developed a phlebitis two weeks prior to delivery. She had been taking vitamin K for some two weeks previous to the development of the phlebitis. Could you tell me whether in a case like this vitamin K will tend to cause phlebitis?

C. N. Talley, M.D., Marlow, Okla.

ANSWER.—In therapeutic doses vitamin K has little if any effect on the coagulation of the blood of normal persons. There is no experimental or clinical evidence that the administration, even in large doses, of vitamin K is followed by phlebitis. Since thrombophlebitis is not too infrequent in pregnant women, one can state confidently that in a case like that described vitamin K would not be significant in the etiology of the phlebitis.

PAINFUL BURSÆ AROUND ISCHIAL TUBerosITY

To the Editor:—Is there any such term as "bursitis ischioglutealis"? This diagnosis was made for pain on the os pubis of one side on sitting, lasting now over some years with intermissions of months. Some years prior to the onset of pain there was prostatitis. Regular and repeated treatment was instituted and the prostate is all right now.

M.D., New York.

ANSWER.—There are several small bursal pouches in the region of the ischial tuberosity. As a result of repeated irritation and sometimes following a traumatic injury there may develop a pronounced bursal swelling with chronically thickened walls. This bursa is so placed between the ischial tuberosity and the gluteus muscle that it would seem quite correct to designate this as an ischioglutealis bursitis, although that term has not been used often enough to become generally well recognized.

ALKALIS FOR SCALDING HOGS

To the Editor:—On page 320 of the May 27, 1944 issue of *The Journal* there is a query regarding the use of lime in scalding hogs. In the reply it is stated that packing houses have discontinued the use of chemicals; that hogs are merely scalded in boiling water and sent through the dehairers. In this connection I want to say that alkalis still are used in all packing plants in the scalding tubs in order to cleanse the carcasses. As suggested by your inquirer, lime is used, as is also soda ash and sodium hydroxide. One authority suggests 100 pounds of pine tar, 10 pounds of caustic soda and 30 pounds of soda ash for a 3,500 gallon scalding tub. It is true, of course, that workmen do not come in contact with the scalding water except in raising the tendon of the hind shank. Scalding is not done at the boiling point as the reply suggests, but at 140-146 F. Dehairing is done with a mechanical device. Some shaving is usually necessary by hand to remove hairs which escaped the beaters.

William J. Loeffel, Lincoln, Neb.
Chairman, Animal Husbandry Department, University of Nebraska.

THE CHANGES IN OPERATIVE GYNECOLOGY DURING THE LAST QUARTER-CENTURY

CHAIRMAN'S ADDRESS

LOUIS E. PHANEUF, M.D., Sc.D.
BOSTON

Much progress has been made in the surgical technic of all specialties in the last twenty-five years. Mass ligation of tissues has been supplanted by careful dissection and the tying of individual vessels. Large suture material has been replaced by fine sutures, with better healing. The advocates of the silk technic have shown that, with careful hemostasis and the use of the finest threads, inflammatory reaction in wounds or incisions so treated is almost entirely absent. There are those—and they probably form the majority of operators—who prefer catgut to silk. Taking a leaf from the book of the silk advocates, they have gradually reduced the size of their catgut until now a No. 0 strand may be used in place of the former No. 2, this having been made possible by the improvement in the manufacture of catgut. With the decrease of foreign bodies in sutured wounds, the severe reaction and abundant serum previously found have been eliminated, resulting in better and more rapid healing. The painstaking dissection of the tissues, the employment of the finest sutures consistent with the amount of tension present and perfect hemostasis are the three general factors which have had the most to do with the improvement of surgery in general.

CARCINOMA OF THE UTERINE CERVIX

Twenty-five years ago radium and high voltage x-rays were just beginning to be selected in the treatment of carcinoma of the uterine cervix. Irradiation then was usually resorted to for the inoperable cases. The radical abdominal hysterectomy to which the name of Wertheim has become attached was the method of choice in the treatment of this malady. It was well known at this period that a simple panhysterectomy offered but little chance of a permanent cure, since in this operation the parametria, the pelvic connective tissue and the iliac glands were left undisturbed. The mortality of the Wertheim operation at this period was high, the fatalities being due in large part to shock, hemorrhage and infection, and the prevention and management of these conditions not being so well understood as they are today. Blood transfusion had not as yet come into its own, the facilities for blood transfusion in the average hospital were very meager to say the least, and in certain cases the blood transfusion,

if given at all, was more of an operation than the hysterectomy itself. The sulfonamide drugs used in the prevention of infection were of course unknown during the period under discussion. The Schauta vaginal hysterectomy for malignant disease of the cervix had but few adherents in America, surgeons here preferring the abdominal route. Considering the constant and rapid improvement in the technic of irradiation, with its low or absent mortality, simplicity of performance and primary results as good as or better than those of the Wertheim hysterectomy, it is not to be wondered at that the latter procedure was practically totally abandoned. As time has gone on and women treated by irradiation have been carefully followed over a period of many years, injuries of the large and small bowel the result of fibrosis resulting in intestinal obstruction at the end of fifteen to twenty years, according to some statistics, have averaged about 20 per cent. Again, deep and refractile ulcers of the bladder have been found after a number of years. This is no disparagement of radium and x-ray therapy, which doubtless have been used in most cases in the treatment of cervical cancer. As one of those who never entirely gave up radical pelvic surgery for irradiation, I have often wondered why an operation like the radical abdominal hysterectomy which had rendered such signal service could be absolutely abandoned. It has always seemed to me that there must be a place for it in the properly selected case. Recently a small number of gynecologists have reasoned along the same lines and have again turned to surgery in well selected cases. Those who are returning to the Wertheim operation today realize that the mortality must be kept at a low figure. This may be accomplished by selecting only group 1 cases, those of women in good physical condition; by cleaning the cervix and minimizing infection by a small preoperative dose of radium, when indicated; by preparing the patient carefully, paying particular attention to the blood; by the judicious use of whole blood and blood plasma transfusion preoperatively, intraoperatively and postoperatively, and by leaving the required amount of one of the sulfonamide drugs in the culdesac of Douglas after covering the raw areas with peritoneum. When this selection and technic are carefully followed, the convalescence of these women does not differ much from that of those who have been subjected to an ordinary panhysterectomy. Radium and high voltage x-rays are still reserved for some cases in group 1 and for groups 2 and 3, and are used as palliative agents in some group 4 cases. Diagnosis of early cancer of the cervix is one of the prominent achievements of the last quarter of a century.

CARCINOMA OF THE UTERINE CORPUS AND FUNDUS

In the management of corporal and fundal carcinoma no such radical change has taken place as in carcinoma of the cervix. A simple panhysterectomy with the

Read before the Section on Obstetrics and Gynecology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

ablation of the adnexa, with or without preoperative radium and postoperative high voltage x-ray therapy, has remained the treatment of choice. Improvement here has also come through early diagnosis. Malignant disease occurs in this area at a more advanced age than it does in the cervix. The advocacy of a diagnostic curettage for women who bleed irregularly at or after the menopause has been responsible for the recognition of the disease in its incipience. Even here irradiation has been of great benefit to a group of women advanced in age whose physical condition does not warrant as extensive an operation as a panhysterectomy. Although radium and x-rays have not shown such brilliant results in cylindric cell as in squamous cell cancer, nonetheless a sufficient number of patients with the condition have been benefited by this form of therapy.

UTERINE MYOMAS

Uterine fibroids are one of the commonest lesions in gynecology. During the last twenty-five years myomectomy has been resorted to with increased frequency. Originally it was thought that myomectomy on account of the increased dangers of hemorrhage and sepsis was a more serious operation than hysterectomy. Recent statistics have shown that through thorough asepsis and careful suturing these difficulties have been overcome, the mortality reported being no higher than that of supravaginal hysterectomy. The great advantage of myomectomy rests in the fact that the functions of menstruation and reproduction are not interfered with, an important desideratum in the younger group of women still in the childbearing age. All statistics show a rather large number of children born of women so treated. The continuance of menstruation is an important factor in the lives of these patients. The principles of supravaginal hysterectomy for fibroids were well established twenty-five years ago, and the results of this method were quite satisfactory. The conservation of the adnexa, when in a healthy state, in performing hysterectomy for myomas on women who have not reached the menopause is a principle accepted by most gynecologists. Our knowledge of the hormones of the ovary and of the fact that they continue their function of internal secretion for a certain period of time if a small amount of endometrium is retained at operation has led to conservation in this respect. That it is essential to maintain a good blood supply to the retained ovaries is a fact recognized by all operators.

The question of supravaginal hysterectomy versus panhysterectomy in the treatment of certain uterine lesions of benign origin in which fibroids play an important role has led to important debates before medical societies when the subject is brought up for discussion. An increasingly well planned and careful follow-up of patients has led to the discovery of a number of carcinomas of the retained cervical stump. It is argued by the protagonists of panhysterectomy that, if the cervix had been removed at the time of the original hysterectomy for fibroids or other benign conditions, carcinoma of the cervical stump could not have developed, a proposition that is absolutely logical and cannot be ignored. On the other hand, the advocates of supravaginal amputation of the uterus agree that the difference in mortality between panhysterectomy and supravaginal hysterectomy is greater than the incidence of stump carcinoma, that the vagina is shortened by panhysterectomy and that in the presence of a retained cervix more satisfactory marital relations may be permitted. In answering these allegations it

may be said that it is true that the mortality of panhysterectomy is considerably higher in the hands of those who perform this operation only occasionally, but the same cannot be said of well trained specialists and experts in its performance. A glance at the statistics for the last ten years seems to prove this point. If the vagina is carefully dissected around the cervix it is not shortened appreciably, and it must be admitted that retaining the cervix for purposes of marital relations is a sound argument and one difficult to refute. One step in the progress of supravaginal hysterectomy during the period under discussion has been the opportunity for careful examination of the cervix, with the aid of a good light, under anesthesia before proceeding with the operation, as benign lesions of the cervix should be healed before or treated at the time of the subtotal removal of the uterus. To accomplish this end many methods have been suggested. These include trachelorrhaphy, amputation, electrocoagulation and cauterization. I have tried all these and come to the conclusion that in my hands thorough cauterization of the cervical canal and portio vaginalis has given the best results. Moreover, the gynecologist in choosing the type of hysterectomy for benign lesions is influenced by the number of stump carcinomas which come to his attention. In my practice, in recent years, the total has almost entirely supplanted the subtotal operation.

In the last decade irradiation by means of radium or x-rays has achieved greater popularity in the treatment of fibroids, but if this method is resorted to it should be an inviolate rule to precede it by a thorough curettage of the uterus in order to rule out malignant disease. In the opinion of many, irradiation should be reserved for those considered poor surgical risks and for those who have reached the age where the ovaries have ceased to function. In the young, whose ovaries should be conserved, and in the good surgical risks, surgery is still accepted as the better method of treatment.

VAGINAL HYSTERECTOMY

The trend toward vaginal hysterectomy in the United States has become more prominent since 1919. Performed before the days of abdominal surgery because of its great safety, it was almost entirely abandoned at the beginning of the present century when abdominal pelvic surgery became popular. During the last two decades it has been reborn, so to speak, and its performance in all gynecologic services is now commonplace. In some clinics its indications have been extended to the point of removing large fibroid tumors by morcellation. Two schools of thought exist in connection with this operation, the first including those who favor the suture method and the second, a small group, sponsored by James W. Kennedy of Philadelphia, including those who favor an improved clamp method because of its simplicity and rapidity. Vaginal hysterectomy plays such an important role in gynecology that it is not likely to be again abandoned.

VESICOVAGINAL FISTULAS

Originally vesicovaginal fistulas were the result of the trauma of childbirth or of protracted labor, and with the exception of those adherent to the pubic rami the operative treatment was not especially difficult since they were usually accessible. With the increase in operations on the pelvic viscera, hysterectomy and operations on the anterior vaginal wall and bladder, for example, the so-called surgical fistulas now greatly outnumber the obstetric. Because of their location, especially those situated high in a scarred and retracted

vaginal vault, their closure may tax the ingenuity of the operator. As a result, vaginal, intravesical and intraperitoneal methods have been devised. Most of these fistulas, however, are operated on, by the gynecologist, through the vaginal approach. Two extremely helpful adjuncts to the operation, probably not resorted to frequently enough, are, first, the Schuchardt incision, which permits such excellent exposure of the upper third of the vagina, and, second, suprapubic cystostomy. The latter, constantly employed by the urologist, has received but little consideration from the gynecologist, who usually inserts a self-retaining catheter through the urethra to keep the bladder empty. In many cases the catheter rests and causes pressure on the recently repaired area. This may militate against healing, whereas draining the bladder suprapubically places the sutured area at rest and leaves it undisturbed. This method is so advantageous in difficult cases that I wonder why I did not resort to it much sooner. The silver wire suture recommended by J. Marion Sims still has a place in the repair of vesicovaginal fistulas. More recently the metallic alloy wire suture, recommended by W. Wayne Babcock, has received deserved attention because of its greater tensile strength and because of the possibility of tying instead of twisting the suture.

TRACHELORRHAPHY AND AMPUTATION OF THE CERVIX

Trachelorrhaphy and amputation of the cervix are still valuable operations, although trachelorrhaphy seems to be losing some of its popularity. The current and useful methods of cauterizing the cervix after each labor, thereby overcoming erosion and ectropion and healing the smaller lacerations, has resulted in the less frequent performance of these operations. It should be emphasized that high amputation of the cervix should not be performed on one who is expected to have more children because of the frequent resultant sterility, because of the increased incidence of abortion and because of the dystocia in subsequent labors.

UTERINE PROLAPSE: CYSTOCELE: RECTOCELE

During the last twenty-five years the progress in this branch of gynecologic surgery has come through a better understanding of the structures that hold the pelvic viscera in their normal position. The modern reconstructive operations are based on sound anatomic and physiologic principles. The supportive structures are exposed by layer dissection rather than by superficial dissection of the surface mucous membrane of the vagina. As might be expected, better operative results have been secured. The operations of uterine suspension and fixation of the uterus to the anterior abdominal wall have definitely decreased in frequency. It has been recognized that fixation of the uterus to the abdominal wall is contraindicated during the childbearing period. In treating women who have passed the menopause there has been a decided tendency to operate entirely through the vagina rather than by the combined vaginoabdominal method in vogue in the early part of the century.

PELVIC INFLAMMATORY DISEASE

Although numerous organisms may be etiologically responsible for pelvic inflammation, three large groups predominate: specific infection, caused by the gonococcus; tuberculous infection, and the large group of pelvic cellulitis for which the streptococcus is generally responsible. It is evident in all large gynecologic services that pelvic inflammation is decreasing. The

sulfonamide drugs are changing and may still further change the course of gonorrheal infection. It has been proved that these drugs limit the extension of the disease. For practical purposes gonorrheal infection in women may be divided into three stages: the initial infection involving the urethra, the vulvovaginal glands and the cervix; pelvic invasion, usually occurring at the time of menstruation, when the organisms attack the endometrium, the tubal mucosa, the ovary and the pelvic peritoneum; and the development of degenerative lesions resulting in hydrosalpinx, tubo-ovarian cyst, adhesions, fixed retroversion and the like.

The treatment of the first two stages is conservative, that of the third stage operative. If the sulfonamide drugs come up to expectations and if the infection is limited to the first stage, the treatment of gonorrhea in women may become entirely conservative and the extensive operative procedures carried out in the third stage may rarely occur. Tuberculosis of the female organs of generation has gradually diminished during the last twenty-five years, doubtless because of the systematically carried out prophylactic measures against the disease in general, its decreased incidence and its earlier recognition. This disorder does not play an important part in pelvic inflammatory disease today. Puerperal infection in the form of postabortal and postpartal pelvic cellulitis still demands the earnest efforts of the profession. Although prophylaxis has reduced the number of such infections, puerperal sepsis still heads the list of causes of maternal deaths in this country. Here again the prophylactic measures are beneficial and the sulfonamide drugs are proving to be valuable in arresting such infections, so that even here the operative treatment may be curtailed.

OVARIAN TUMORS

In connection with ovarian tumors, the progress established during the last two and a half decades has been due to better classification and the recognition of certain of the rare ovarian new growths. The significant work of Sampson and others has placed pelvic endometriosis on a sound basis. Although there is some disagreement regarding the etiology of endometriomas, gynecologists agree on the method of treatment. There are no great differences of opinion as to the operative management of ovarian tumors. It is the general opinion that small multiple cysts, follicular cysts and lutein cysts seldom need operative intervention. As far as the true neoplasms of the ovary are concerned, the opposite obtains, since a high percentage of the benign new growth are known to develop a certain degree of malignant degeneration and since it is obvious that the malignant ones should be operated on as soon as they are diagnosed. Whereas uterine myomas may be kept under observation, with safety, for an indefinite period of time—a significant number regressing at the time of the menopause—the same cannot be said of ovarian neoplasms because of the strong possibility of the development of malignant changes, slight or extensive. It is a safe rule, therefore, to follow the custom instituted many years ago—namely, that the treatment of ovarian neoplasms be operative and that operation be performed as soon as the diagnosis has been established.

SUMMARY

The last quarter of a century has shown significant improvement in surgical technic, with emphasis on careful dissection and ligation of individual vessels with fine material rather than mass ligation of tissues. The treatment of carcinoma of the cervix has changed from

surgery to irradiation with the return to the radical pelvic operation by a few gynecologists in early cases and good surgical risks. Carcinoma of the uterine corpus and fundus has remained a surgical lesion, surgery, however, having been complemented by irradiation. Improvement in the operation of myomectomy has resulted in more conservative management of these lesions in the young; supravaginal hysterectomy still remains the common method in use, while an increasing number of gynecologists have turned to panhysterectomy as a prophylactic means against carcinoma of the cervical stump. Vaginal hysterectomy has been reborn and improved and has now become a commonplace procedure. The increased number of surgical vesicovaginal fistulas has been responsible for the elaboration of new technics in the cure of this lesion.

Trachelorrhaphy and amputation of the cervix are less frequently done, these having been replaced in many cases by cauterization and electrocoagulation. A significant advance has been made in the surgical treatment of uterine prolapse, cystocele and rectocele through better anatomic understanding of these lesions and by reconstructing the deficient supports through the vagina rather than by depending on abdominal suspension or fixation of the uterus. Pelvic inflammatory disease has been handled more and more by conservative methods, and the sulfonamide drugs seem to show great promise in lessening and eradicating this condition. Ovarian tumors have been better classified, the rare tumors have been discovered, the tendency of malignant changes in these neoplasms has been emphasized and their early ablation has been strongly advised.

270 Commonwealth Avenue.

TREATMENT OF WAR NEUROSES

LIEUTENANT COLONEL ROY R. GRINKER

MEDICAL CORPS, ARMY OF THE UNITED STATES

Major Spiegel and I have described brief, dynamic psychotherapy as applied to various types of war neuroses.¹ We have indicated the standard technical methods found by experience to be the most effective in the treatment of typical cases. However, psychotherapy is always an individual procedure, variable for each patient, requiring on the part of the therapist not only scientific knowledge but skill or art and a sense of timing. The following steps are carried out in most cases:

1. Release of repressed emotions in a process of so-called "abreaction."
2. Support of the patient's weakened and regressed ego through identification with the therapist's strength.
3. Desensitization from the memories of the anxiety producing situations by repetitive recounting of traumatic experiences, as the therapist helps the ego to discriminate between past danger and present safety and between dangers of the world of reality and inner anxieties.
4. Neutralization of the severe superego reaction of guilt to the actual, or sense of, failure.

From the AAF Convalescent Center, Don Ce-Sar Place, St. Petersburg, Fla.

Read in a panel discussion on "Neuropsychiatry" in the General Scientific Meetings at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 13, 1944.

1. Grinker, R. R., and Spiegel, J. P.: War Neuroses in North Africa, the Tunisian Campaign (January-May, 1943). New York, Josiah Macy Jr. Foundation, September 1943; Narcosis: A Psychotherapeutic Method for Acute War Neuroses, Air Surgeon's Bull. (No. 2) 1:1 (Feb.) 1944; Brief Psychotherapy in War Neuroses. Management of Neuropsychiatric Casualties in Zone of Combat.² War Neuroses in Flying Personnel.³

5. Instilling insight into the relationship between the neurotic reactions to war and the past character and personality trends.

6. Encouraging the ego in its experimental attempts to regain mature attitudes and to attempt adult activities, thereby giving new confidence to the weakened and regressed personality.

In order to describe these procedures in a concrete fashion I have chosen to present an abstract of the actual therapeutic maneuvers in the treatment of one patient:

REPORT OF CASE

Depression with anxiety of one year's duration relieved by pentothal narcosynthesis and brief psychotherapy in one week.

A captain aged 25, who was sent to the Convalescent Center because of objective symptoms of depression, presented an expressionless face; his muscles were quite rigid, indicating a great deal of tension. He did not volunteer much information and never smiled, and his speech was retarded. The patient had been a flight leader in a pursuit squadron and had fought successfully until about his twenty-fifth mission, when a friend who had been flying on his wing went up in flames. However, he stated that he continued fighting and successfully completed his tour of duty, although feeling bad and depressed. He returned to the United States, refusing the chance of remaining as commanding officer of a squadron. He had been reassigned to a job in the United States which he liked very much and wanted to keep, but his depression continued and was accompanied by severe startle reactions. When any one came into his room and made a sudden noise or turned on the light he would jump out of bed with great anxiety. In addition to the depression and its concomitants, there was considerable insomnia with battle dreams, which repeated some of the very severe traumatic incidents of his combat experiences. However, he maintained fairly good control of himself and continued to fly. He attempted to decrease the anxiety and depression by drinking, but the only result was an increase in anxiety. He stated that he tried hard to forget his experiences but found it impossible.

During this initial interview I learned that he was single, a university graduate who studied hard, made excellent grades and was given a fellowship in animal genetics which he could not continue because he entered the Air Forces. There was no history of any previous depression and no incident that showed that he could not adjust himself to his normal experiences and environment.

That afternoon I gave him 0.25 Gm. of pentothal sodium intravenously. He was then told that he was up in the air on a strafing mission and that the man on his wing was aflame, and then I commanded "Go ahead and talk." Immediately he went into an emotional reaction, shouting to his friend, whose name was Granny, to "pull up and bail out."

"Why doesn't he pull up, why doesn't he bail out? I hope he doesn't think it's my fault. He's such a nice boy. Such a swell fellow. I hope I'm not responsible for his death. We were together all the time. He lived in the same tent with me and would share anything that he had. When we were on low rations he would give as much as he could to every one else." Accompanying all this were tears and sobbing and repetitions of "I hope he doesn't think it's my fault. He wasn't a good flier. Oh, if I had only picked out another spot, a safer target, but that is where they told me to go, right over those trucks. If I had gone in some other place he wouldn't have got it. Why did he do it? He should have stayed in formation. He didn't stay where he was supposed to. He came up and took the lead position with me. Maybe I should have given a talk before we went, about staying in formation. Why didn't I do that?"

Then he talked about the letter they wrote home to Granny's family and how he couldn't bear to read it. That would start it all over again. "I can't get him out of my mind. I couldn't see his family because they probably had forgotten and I didn't want to stir them up." In this fashion he went over and over the traumatic situation, crying and sobbing.

This is the phase of abreaction.

As this reaction subsided he was allowed to close his eyes and sleep for a few moments. Then I handed him a light cigarette and awakened him. He looked at his watch and stated,

"I must have been asleep. I had a dream about Granny." His pillow was wet with tears. He said "Gosh, I perspired a lot."

I told him "No, you were asleep for only a few minutes but you talked to me about Granny and you told me all about it. Let's talk about him some more."

Then in a conscious state he went over the situation again, just as he had done when asleep, but one more bit of information was elicited; Granny was not appointed a regular flight leader because he was a mechanical flier; instead, the patient was given the job. Then the patient talked about another boy who crashed in a low level flight, maintaining radio silence according to instructions although he was in need of help. Then he told of feeling bad about killing the Germans. I ended the interview by telling him that he had assumed a responsibility for the death of Granny that did not seem to be based on fact.

Identification with the therapist and desensitization has begun.

The next morning the patient entered the interviewing room and stated "I feel like a load has been lifted from my mind, like a great relief. I slept well last night, awakened once and went right to sleep again. I had no dreams. This morning I feel good." There was a silence. Then he said "I guess I blamed myself unnecessarily." I said "Yes you did. Now let's try to figure out why you blamed yourself. Tell me something about your background." The patient then told me he lived on a farm of 650 acres. His father was a successful farmer who made enough to enable four children to go to college. The first child was born dead, the second was the patient and then there were two sisters each two years apart and the oldest two years younger than he. He had one brother nine years younger. The mother was very mild mannered and very religious. The children went to Sunday school and church, though not forced to do so. The father was very kind and gentle but strict in his attitudes. He rarely spanked the patient, but he expected him to live up to his responsibilities. If he did not, he would look pained and disappointed and tell him "This was your job," and then do it himself, which the patient stated was worse than a spanking. He was always on very good terms with his father and would rather work with him than any one else.

He then began to talk about his commanding officer and told how this man was an exceptionally strong leader; a person who went on the most dangerous missions himself; a man who was fair and expected every one to do his job.

I said to him "Your C. O. was very much like your father." The patient stated "You know, I often thought he was like my father, doing things he wasn't supposed to do and doing everything to help us but expecting the best from us. Of course not in the same way because he was a fighter." I said "Now let us summarize the things for which you blame yourself. Granny's death—but you were ordered to hit the target even though dangerous; you could do nothing else and could not be responsible for his death. Secondly, you blame yourself for not giving implicit formation instruction, but you were all experienced fliers and had been trained in formations for six months and every man knew his position. You blame yourself for killing the Germans but you know that was to save the lives of our own troops. You blame yourself for the boy who crashed on the low mission, but it was agreed beforehand that radio silence was to be maintained. You blame yourself for not communicating with Granny's family, but you know that it is not good to stir up a sorrowing family again. So you have a lot of disapproving attitudes toward things which are not really your fault. You behave as if you were still reacting to a disapproving attitude that your father might have had toward you. You behave as if your father's image were looking at you with a disappointed expression."

Here we see a beginning neutralization of a severe superego.

The patient said "Well, I have always taken responsibilities and duties seriously. I have never been able to feel that I did give my best unless I worked terribly hard."

Then I stated "And now your behavior, which is depressed and completely unhappy, is just as if you were intent on

punishing yourself and never letting yourself have any fun or pleasure."

The patient stated "That's it. I can't enjoy things. I wonder why I take his death so seriously." I stated "Yes, I wonder why" and terminated the interview.

The next day the patient entered the interview smiling and stated frankly "I must say I haven't felt so good as I feel now for a long time. I slept well and had no dreams." He felt as if he could carry on. He now realized that he took his responsibility too seriously but always had felt as if he didn't want to let any one down and then told about a younger pilot, 21 years of age, whom he had taught to fly formation. The younger pilot looked up to him as an older man or father. I said "Something like your younger brother," and he answered "Yes, he used to think I was a great guy. I taught him how to shoot, how to hold a gun and how to play all sorts of games. Our C. O. always spoke quite frankly about his opinion of the conduct and performance of the boys; he either disapproved or complimented. If a fellow did his work properly and if he asked for a day off he always got every consideration."

I explained to the patient then because of guilty feelings he was punishing himself for Granny's crash (which had happened one year before). I explained to him that this feeling had persisted without any cause in reality. Therefore, this sense of guilt and the punishment which he had been giving himself must be due to some inner feeling and that it was not possible to master such feelings unless we unearthed them and brought them to light.

I told him "Now you have told me nothing but good things about Granny, you told me how attached you were and what a fine fellow he was, but I think your guilty feelings about him are due to some negative attitudes toward Granny that you have not yet discussed. Perhaps these feelings were unconscious and a source of your sense of guilt."

This step is the beginning of the loosening of unconscious hostility derived from part of his precombat personality.

The patient then said "Of course no one is perfect, but Granny was the easiest person to get along with. He drank frequently and had to be taken care of. Once when we were in the desert and got drunk Granny tore up the tent in the middle of a sand storm. There was a family quarrel with the four tent mates."

I then drew his attention to the fact that Granny was not made flight leader. Was Granny envious of the patient? He reconstructed the flight; Granny was flying on the left wing of the patient, who was the leader. Granny flew on the left slightly behind, but he veered to the right and forward, to accompany the patient in the lead position. I asked him whether he interpreted this as if Granny were out to take the lead as a sort of rebellion. He said he didn't think so, but that he didn't give way because he wanted to maintain the proper formation in the flight. Then he said "Maybe that is why I feel so guilty, because I didn't give way." The result was that Granny was hit by flak and slid over the patient's plane to the right, on fire.

I told him "I think that there are some definite unconscious negative feelings toward Granny which might be responsible for your sense of guilt, and hence depression, and we will take that up in the morning."

The next morning the patient entered the room, at ease and in good spirits, and said "Colonel, I have been thinking a good deal about the situation of Granny, and some clue you gave me yesterday brought me to some sort of a conclusion. Probably it is silly, you might not think it is important, but I have been thinking about it." [When a patient says he is going to tell you something silly you prick up your ears because it is probably going to be the most important thing you will hear.] "I always decided that I wanted to do things and get ahead. I was very ambitious. I wanted to be better than just average and when I decided on any ambition I worked very hard to accomplish it. Sometimes I would win and sometimes I would lose but I would always work for whatever I wanted. When I was in school there were four of us on a cattle judging team. I wanted to be top man, but there was another fellow on the

team who lived with me and he was awfully good. I had to fight it out with him. We fought it back and forth all year round. In my junior year I was able to beat him. The next year he beat me. There were no hard feelings about it. It was competition but we still were friends."

The patient now begins to test his own inner attitudes in the light of reality.

The patient then repeated several other incidents of competitive relationship with other men and it became clear that he took no pleasure in winning over people who gave him no struggle. He always wanted to win out over some one who he felt was superior to him. "When I joined my outfit it was the same way. We had a C. O. who believed that the leadership in the squadron should come from the boys themselves. There were eight places for flight leaders and the men had to win the job. Even after a man became flight leader he had to work hard to keep it. We were always practicing, practically all the time. Two or three would go up and try to outfly one another. When we finally went overseas I wasn't able to take a lead position but I became an assistant flight leader. I was disappointed but worked hard just the same. Finally there were eight of us who were flight leaders, including Granny and myself. But we weren't always given the job of leading the flight. Our C. O. wanted to see how we were able to fly under somebody else's orders. We didn't always fly leader, we frequently flew wing. Once I went up with our C. O. to try to outfly him. I fought him hard and I beat him. When we came down I didn't say a word to anybody that I had beaten my C. O."

You now see how the patient has arrived at the logical conclusion without a direct interpretation. He has worked this thing out himself. There has been a certain amount of direction in the interview, but he has been able to think along the directed lines all by virtue of the fact that he has had an initial emotional release and ego support. But the release alone was not sufficient. He still didn't know the reason for the load of guilt that he had been carrying.

I then explained to the patient the nature of unconscious attitudes which were not tempered and modified by civilized realities; that our unconscious aggressions which arose from the instinctual depths within us were derived from our animal backgrounds. Sportsmanlike competition was a civilized modified type of aggression, but the real hostile competitive spirit is still based, as far as the unconscious is concerned, on the concept "to kill or to be killed." As a result, victory in competition would mean, unconsciously, as if the defeated person had been destroyed as the direct result of an unconscious wish to be rid of that person. Hence, when competition was followed by the death of an individual, the person felt actually as if he himself had killed that individual.

He grasped this interpretation and in the same interview was given another pentothal injection. He immediately started out by saying "I used to think I was responsible for Granny's death. I used to feel as if it were my fault. I know now that it is just one of those things that happen and I couldn't help it. He was a fine fellow. I was scared to go on that mission. He and I went into the mess hall that night for some supper, but we just nibbled; we couldn't eat. I had no cigarettes, but Granny had two packages and gave me one of them. I smoked half a package of cigarettes. Granny was generous like that. I was terribly nervous. It was a dangerous target, but off we went in a tight formation. There was a terrible amount of flak over the target. The trucks blew up and I felt good when I saw it. I don't know why Granny came over and tried to take the lead from me. I flew under his lead the day before and I stayed in formation. I can't understand why he broke formation and came up toward me and then got into a heavy flak position. But I didn't give

ground. I know now we were jealous of each other and we were really fighting against each other for the job."

When he awakened he felt a little dizzy and thought I had been sleeping. We summarized the whole material of the interview again before terminating the session.

The next day he came in and said he felt perfectly well. He slept soundly all night, had no dreams and felt that a great load had been lifted from him. He wants to go back to duty and feels he can carry on. When he went home for overseas leave his people recognized there was something the matter with him and didn't ask him any questions. The result was that he kept all the experiences to himself and deliberately tried to forget, but there was always that load on his stomach. He now understands that the only way one can forget is to suffer the pain of remembering first. He remembers episodes he thinks are funny and amusing, incidents that happened in his squadron overseas. He is beginning to remember and talk about little experiences. Prior to this he had not been able to think about these because they always led his mind into situations which became painful. "It is silly for intelligent people to let things bother them the way I did." His ego now has confidence in its strength and can dwell on the past without anxiety.

The question arises whether we should go on in further interviews and therapy to bring to consciousness the obvious unconscious hostility he had to his own father, or should we stop at this moment and return him to duty. We have been successful in removing the load on this man's personality which he has been carrying for a year. This load was the direct result of his combat experiences acting on his specific character and personality. As a result of the incorporation within his personality of the idealized figure of his father, we have a man who has been a successful student, a successful pilot and a successful leader. We can predict from this personality structure that he will probably continue to be successful in life. Along with this compulsiveness toward success we have to recognize the severity of his ego ideal, which would make him some trouble if he came into a situation in which he could not be successful, but we have already dislodged and disturbed that ideal. The therapy has been directed largely to weakening the severity of his father's attitudes to permit him to accept his repressed aggressions. That is the load that is off his chest. We can be assured that the loosening and easing of this pressure on him will continue perhaps to the extent that his ego ideal will be strong enough but not too severe. Therefore we did not treat him any further but returned him to duty. Six months later reexamination revealed him to be entirely well and competently performing his flying duties.

In the therapeutic process there was an initial loosening of the emotion, the substitution of a new, less severe superego and then the confrontation of the old guilt with reality, which forced the patient to look inside himself for the source of his reaction. It might be said in many cases that it is harder for a man to face his own unconscious than to face the fire of the enemy, but it must be endured if recovery is desired.

Overseas we were concerned with the direct and demonstrable effect of combat.² In the time that elapses before these men return to the United States a change seems to take place in the pattern of the neuroses. Old

patterns of neurotic behavior seem to engulf the newer reactions, and the total picture stands out sharply. The reaction to war is seen to be a repetition of old reactions to previous conflicts.³ There are no great resistances against the release of the old attitudes which have been mobilized by the new war situation. Hence our therapeutic achievements are frequently more than a removal of recently developed anxiety but often include an unexpected beneficial reorientation of the total personality. The technics are not difficult nor are they lengthy, but they require a thorough knowledge of the dynamic forces operating in human personality.⁴

THE MANAGEMENT OF HEAD AND SPINAL CORD INJURIES IN THE ARMY

MAJOR WILLIAM H. EVERTS

Chief, Neurology Branch, Office of the Surgeon General
AND

MAJOR BARNES WOODHALL

Chief, Neurosurgical Section, Walter Reed General Hospital
MEDICAL CORPS, ARMY OF THE UNITED STATES

The management of head and spinal cord injuries can never be a stereotyped, fixed method in the army. The type and degree of injury, nature of the traumatizing agent, mechanism of the trauma and circumstances under which initial care must be rendered vary so much that good clinical judgment rather than strict procedure is the all important factor in care of such injuries. The echelon for care of these cases in combat is the same for all types of trauma. The wounded soldier passes through the battalion aid station and clearing station of the division, and thence back to an evacuation hospital. A field hospital unit may, under some circumstances, be attached to the clearing station for the definitive attention of the most seriously wounded, but usually such detailed care is rendered at the evacuation hospital. From any one of these medical stations the soldier may be returned to duty with his own unit after receiving necessary care. Patients who cannot be promptly restored to a duty status or any who need prolonged medical care are sent back to a general hospital, from which those who are ultimately restored to a duty status are sent to replacement depots for reassignment as casuats to other units. Those who are unfit for any duty or for foreign duty are returned to our named general hospitals in the United States. Most of the latter hospitals are rehabilitation centers where any and all definitive medical and surgical attention can be rendered to our troops. From this echelon, troops are either discharged from the army after receiving maximum hospital benefit or are sent to special convalescent and reconditioning centers to be restored to a duty status.

The management of head and spine injuries in the overseas noncombat areas is essentially like that in the American zone of the interior; viz., hospitalized and definitively treated promptly without the factor of rearward movement away from combat area.

HEAD INJURY

The general size of the head injury problem may be ascertained from a review of battle casualties for the year 1941-1942. For that year head injuries made up 5.9 per cent of all wounds sustained. This figure would, of course, be slightly higher if one included those killed in action, for, in those, wounds of head, chest and abdomen run high. In general, then, it may be said that 6 of every 100 battle casualties are head injuries. If we break this down further, we note that slightly more than three fourths of this total group are closed head injuries with or without a simple skull fracture and the remainder are open head injuries of varying severity.

Closed head injuries in all echelons receive conservative therapy, varying according to the necessity or judgment of the medical officer. During the acute phase in the first seventy-two hours the patient is placed on a modest fluid intake, 1,500 to 2,000 cc., and a light diet. A lumbar puncture may be done if deemed therapeutically necessary; otherwise it is usually not done until after the first forty-eight to seventy-two hours, when it may be desirous to know the pressure and whether fluid is blood stained. Sedatives are used with caution, since a simulated stupor can easily be produced in this acute phase following a concussion, or again it may mask bleeding. Hypertonic solutions are not used routinely but are used when edema is evident and producing symptoms after the first day or two of injury. Normal serum albumin is probably the best hypertonic solution and has been widely distributed through army hospitals. X-ray films of the skull are always taken, but until the patient's shock and primary condition is first treated, films are withheld for the first day or two, unless there are very pertinent reasons why an x-ray should be taken sooner. In some of the forward stations closed head injuries have been evacuated in ambulatory fashion as soon as clearly conscious. In general, however, the usual program of bed rest is immediately instituted and maintained for two or three or more weeks according to the severity of the head injury, the latter judgment being based on the duration of loss of consciousness and the degree of disturbance in the temperature, pulse, respirations, pupillary abnormalities and focal neurologic signs. The same criteria are also utilized prognostically as to whether the soldier will be rehabilitated for duty or returned to the zone of the interior. A number of installations here at home have carried out a somewhat more active program in management of the closed head injury group and with gratifying success; viz., starting rehabilitation soon after stabilized, clear consciousness is regained. Thus, in milder cases latrine privileges may be permitted after the first twenty-four to seventy-two hours and then a graduated program of activity over a period of the next ten days with return to light duty in about two weeks and full duty in six. Incidence of post-traumatic syndromes appeared especially low when treated in this manner.

We have observed that patients having mild head injuries are often more likely to complain of headache, dizziness, insomnia, irritability and trouble in concentrating than those receiving a more severe injury. Also it must be remembered that treating a head injury patient who may be emotionally unstable, in an overseas theater, is just a bit different prognostically at least from treating the same patient here at home, since the element of secondary gain is a potent factor in production of a neurosis in many of these overseas cases. Particularly does one see this in the group alleged or

actually to have suffered a concussion due to blast. Many of those returning from overseas allege blast concussion as a cause of their persistent headache and associated nervous symptoms. As a matter of fact, concussion due to blast is quite unusual. The individual who has suffered organic brain damage due to blast invariably gives a history of having his breath knocked out, of coughing up bloody sputum, bleeding from the ears and nose and a period of complete loss of consciousness. On examination, these soldiers show flash burns, fissuring of the skin, perforated or hemorrhagic eardrums, conjunctival hemorrhage, signs of intrathoracic or abdominal pathologic changes and focal or general signs of organic damage to the central nervous system. All head injuries receive a most painstaking neurologic survey in the general hospitals, including electroencephalography, pneumoencephalography as indicated, mental tests and psychiatric studies during the course of hospitalization.

As for the outcome of closed head injuries, we have no definite overall figures. However, we do have data on several series of sufficient size to get a fairly good picture of what is happening to this group. In one overseas series of 131 patients, 79 per cent returned to full duty after an average hospitalization of twenty-five days, 15 per cent developed post-traumatic syndromes for which they were evacuated to the zone of the interior, and 6 per cent were still being rehabilitated. Of the group that are returned to the zone of the interior, the majority are discharged from the army, many with a pronounced psychogenic display, others with post-traumatic encephalopathies of such degree that they could not be rehabilitated for duty. Approximately the same statistics apply to the continental head injury group as far as we can ascertain, though again we have no accurate data on this.

Open head injuries comprise about one fifth of all head injuries. Few statistics are available at present concerning mortality or morbidity rates in head injuries caused by missiles in the American army personnel. In one series of 22 acute craniocerebral injuries of open type (dura torn, cortex injured, metallic fragments in the brain and several with grossly damaged brain and osteomyelitis of the skull) there were no deaths after operation. 36 per cent were returned to duty, 59 per cent were evacuated to the zone of the interior and 5 per cent remained in the hospital under continued rehabilitation after a period of sixty-eight days.

In all probability, our overall figures will compare favorably with those mortality rates reported by the British. Eden,¹ in his posthumous paper, gave a mortality of 23.6 per cent in 102 penetrating wounds of the brain and but one death in 208 nonpenetrating injuries. Ascroft² has reported a 15 per cent mortality in 292 penetrating injuries and two deaths in 224 nonpenetrating cranial wounds. In the American forces, serious head injuries sustained in combat are given early definitive treatment either in field hospitals manned by skilled auxiliary surgical units or more often in evacuation hospitals by trained neurosurgeons. The most important complication remaining is that of infection, particularly in those cases in which early and complete débridement of cranial wounds has not been accomplished. In Eden's and Ascroft's series, fatal infection supervened in 3.7 per cent and 10.8 per

cent respectively of patients operated on. This may be compared with the figure of 36.5 per cent in Cushing's series of grave head wounds treated on the western front in 1918. British experience has suggested also that chemotherapy with sulfonamides in fresh wounds does not reduce incidence of infection when débridement is delayed.

Two new substances, penicillin for control of infection and fibrin foam for control of hemorrhage, are now receiving clinical trial under combat conditions. In the battle of Sicily, 25 cases of cranial wounds infected from three to eight days were treated with penicillin by British neurosurgeons.³ Two patients died a few hours after admission to the hospital, and there was a total of five deaths, a remarkably low mortality rate. Obviously, penicillin therapy in such grave infections is a promising method of adjuvant treatment. In 13 brain abscesses and similar formidable cranial infections treated with the aid of penicillin at Walter Reed General Hospital during the past year, there were only three deaths. In these cases it was proved conclusively to attending surgeons that surgical drainage must be continued during the period of penicillin therapy and that penicillin therapy alone is inadequate.

Fibrin foam⁴ for control of hemorrhage from central and peripheral nervous systems has been used at Walter Reed General Hospital in approximately 200 cases, including such operations as formal craniotomies for tumor, repair of skull defects, compound depressed fractures of the skull with cerebral laceration and in peripheral nerve anastomoses and grafts. It is a promising method of hemorrhage control, particularly from the brain that has been lacerated by trauma or operative manipulation. As the supply increases, overseas neurosurgical units will be supplied and cerebral débridement will be especially facilitated by its use.

When the patient with a healed open head injury reaches the zone of the interior and is admitted to one of our neurosurgical centers, he presents one of two problems, and frequently both. The first comprises an evaluation of the extent of the existing cerebral injury in relation to future military duty or to disposition to another status. This is carried out by detailed neurologic and psychologic studies augmented by electroencephalography and pneumoencephalography. The second problem is that of repairing skull defects in otherwise recovered individuals for the purpose of completing rehabilitation for duty. The repair of such skull defects with tantalum plates 0.015 inch in thickness, by inlay or other technics, has been accomplished on 35 patients at Walter Reed General Hospital during the past year. Half of these patients have thus far returned to a duty status.

Before the skull defect is repaired, evaluation of the existing cerebral scar is attempted. In none of these cases was post-traumatic epilepsy a feature and, indeed, this complication of an open head injury has thus far been of minor significance. Records of cortical electrical activity taken through the tantalum plates are unchanged when compared with preoperative records. There is no technical aspect of tantalum plating that would preclude craniotomy for resection of an epileptogenic scar at a later date. Prophylactic excision of such scars is not considered feasible.

SPINAL CORD INJURIES

Spinal cord injuries constitute slightly less than 1 per cent of all battle casualties. No compilation of data is yet available. From one very carefully studied series of 41 cases incurred in battle zones,⁵ some pertinent information may be drawn. Eighty-five per cent of this group were incurred in battle, 15 per cent in combat zone accidents. Over one half occurred in the infantry (infantry 15 per cent, field artillery 19 per cent, armored division 10 per cent, medical corps 5 per cent, engineering corps 5 per cent and all other units 15 per cent), one half occurred in the thoracic spine (cervical 7.5 per cent, thoracic 55 per cent, lumbar 35 per cent, sacral 2.5 per cent), three fourths were caused by foreign bodies (shell fragments twice as often as bullets) and the remainder by fracture. Sixty per cent of those caused by fracture occurred at the 1st lumbar and the remaining 40 per cent very nearby (9th, 11th and 12th thoracic).

Incomplete lesions of the cord were more common than complete lesions, this referring to a functional and not an anatomic lesion. Lumbar lesions were the least serious, since often it was a compression fracture and only a root involvement in this region. Sensory examination was the most accurate guide as to the level and bladder signs the best guide as to severity of the lesion; this was also a good indication for the urgency of operation. Bedsores developed in cord injuries at any level but most frequently in the complete cord lesions in anesthetic areas. X-ray examinations were a preoperative necessity, though often they did not fully indicate the degree of bony damage. Spinal manometric tests were of value in determining whether and when to operate. Of the 10 cases of fracture, 5 showed a complete block and 3 incomplete; in 2 no spinal tests were performed. The period of elapsed time from injury to surgery in these more severe lesions of the cord varied from eight hours to several weeks. The delay for the most part being due to other severe injuries, presence of infections, late onset of symptoms and, in a few, slow evacuation to the hospital. Operation was performed in a total of 31 cases, of which 12 were complete and 19 were incomplete lesions. There was improvement in all incomplete lesions operated on and no improvement in any of those that were complete. Of those in which operation was not performed, improvement occurred in 1 incomplete case and none of the complete showed improvement. Best results were obtained in those cases in which the pathologic condition was mostly extradural. No definite correlation could be made between good results and a short time interval for operation, since the cord showed a surprising ability to recover after long intervals in the incomplete lesions. The reasons for operation on complete lesions were cerebrospinal fluid leaks, presence of block and x-ray evidence of cord compression. There was a total of four deaths in this group of patients. All were complete lesions of the cord, and death was due to pneumonia and lung abscess in 1 (at the level of the 2d thoracic), pulmonary emboli in 2 (level of 6th and 12th thoracic) and the fourth patient, with a lesion at the 12th thoracic, died three months after injury, no postmortem being done.

From these cases it was learned that spinal cord injuries suffered mostly from the chain of evacuation. It was not so much the number of hospitalizations but the time spent in traveling which was so damaging to

cord injuries. Bedsores developed frequently during postoperative evacuation or enlarged rapidly if already present. Circular casts were wholly unsatisfactory, and only bivalved casts are now being used during transportation. The majority of such injuries reach the zone of the interior for convalescence and disposition in a stable neurologic status. The original wounds are healed and definitive surgery has been accomplished. In addition to a reevaluation of the neurologic status, there remain the problems of bladder infection, decubitus ulcers and supportive nursing care in particular cases.

It is unwise to assume in every instance that the need for restorative neurosurgery has passed. Decompressive laminectomy is futile in late lesions of the spinal cord proper but may be of benefit in the region of the cauda equina. In 2 instances of compression of the cauda equina by incompletely reduced dislocations of the lumbar vertebrae, laminectomy performed at Walter Reed General Hospital has relieved pain and possibly played a role in a subsequent tardy and partial restoration of function. In 1 instance of complete section of the cauda equina by a missile, extremity pain was reduced in intensity by neurolysis of the extensive scar. Stabilization of a fracture-dislocation of the cervical spine may be necessary. In a rehabilitation hospital, however, the major task of definitive neurosurgery has passed.

Primary among the problems besetting the spinal injury is that of bladder dysfunction and subsequent bladder infection. Patients are received with indwelling urethral catheters or with perineal urethrostomies or suprapubic cystostomies. The duration of transport and concomitant difficulties of treatment during this period of time may impair the efficacy of urethral drainage. At Walter Reed General Hospital⁶ tidal irrigation is practiced through a urethral catheter with maximum and minimum pressure of 12 and 6 mm. of mercury, boric acid being used as an irrigating medium. In cases requiring long continued drainage, perineal urethrostomy is performed. Suprapubic cystostomy is reserved for those cases in which urethrostomy is not practical because of stricture, large vesical calculus formation or prostatic abscess. Repeated cystometry is done for evaluation of returning bladder reflex activity.

The use of the Stryker turning frame has prevented the occurrence of fresh decubitus ulcers, promoted the healing of those already present and facilitated to a profound degree the nursing care of these patients. Suspension of the feet, freeing them from contact with the frame or bedclothes, and frequent and effortless turning of the patient promote nutrition and healing of pressure areas. Bed linen change offers no problem on such a frame. Physical therapy of the affected musculature is made easy by the height of the frame and the ease of turning the patient. The frame may be transported readily for x-ray studies and, finally, all necessary nursing and therapeutic movement of the patient may be accomplished by a single attendant.

Early grafting of the decubitus ulcer after surgical and chemical cleansing of the wound reduces bacterial infection and concomitant drain on the patient's resources. Such massive grafting has been carried out with split thickness grafts secured with the Padgett dermatome. Although denervated grafts are peculiarly susceptible to the adverse influences of soiling and pressure, they do well with the aid of the Stryker frame.

6. Lewis, L. G.: Treatment of the Neurogenic Bladder After Acute Spinal Injury, *S. Clin. North America* 23: 1505 (Dec.) 1943.

Rehabilitation is in part carried out by the physical therapy department and later in the reconditioning programs for those being prepared for a return to duty. Otherwise, when maximum hospital benefit has been achieved, they are discharged to their homes or to a Veteran's facility. Certainly it cannot be said that any striking advance has been made in the late care of spinal cord injuries, yet application of the factors noted has reduced the subjective distress of these unfortunate individuals and made possible their continued care in large numbers.

SUMMARY

It may be said that head and spine injuries occur with moderate frequency in modern war and present a serious problem of management when they are of the open type head injuries or more severe variety of spinal injuries. The description of the echelons of evacuation and the management at each level has made it apparent that early skilled medical attention is rendered to all acute craniocerebral and spinal injuries in every echelon. In general, it may be said that closed head injuries do best if given early progressive activation and early return to light duty. The more unstable of this group thus do not as readily become ensnared in a compensating neurosis. Open head injuries remain a problem from the standpoint of degree of encephalopathy and repair of skull defects. The medical department has anticipated the ever increasing problem of head and spine injuries with the rising tempo of the war, and as time goes on more data regarding definitive treatment and general management will be forthcoming.

PSYCHIATRIC EVALUATION OF THOSE RETURNING FROM COMBAT

LIEUTENANT COLONEL JOHN M. MURRAY

Consultant in Neuropsychiatry, Office of the Air Surgeon
MEDICAL CORPS, ARMY OF THE UNITED STATES

Reports from overseas theaters indicate that the incidence of psychoneurotic manifestations induced by the physical and emotional stresses of war are frequent occurrences. In the theaters of operation various technics have been devised for the management of these cases with due regard for the severity of the illness and the difficulties of therapeutic endeavors under trying local situations. Oftentimes mere rest and reassurance restore to active duty the men with less severe reactions. Other more serious cases are rehabilitated for non-combat duty in the rear of the fighting lines in the theaters of operation. Still other cases are of such severity that return to this country is necessary. As the war goes on the occurrence of these cases will probably continue. There are also large numbers of men who have completed a prescribed tour of duty in the theaters of operation and who, pursuant to War Department policies, are rotated back to this country. A certain percentage of these men show evidences of persistent symptoms akin to those common in civilian psychoneurotic illness. It is clearly evident that the problem of the care of these men is a most important and pressing one and that our programs for this care will soon need to be fully developed.

The Army Air Forces found it necessary early in the war to adopt a rotation policy for its flying crews. The dangers and hardships of modern combat flying are so great that practically all authorities of the A. A. F. and the R. A. F. were in agreement on this need. The human machine can stand just so much and then it needs a period of "being put out to pasture." A certain percentage of these men returning from overseas on rotation policy showed evidence of persistent psychoneurotic symptoms. This state is diagnosed at this time as "operational fatigue," which is by definition a reactive state resulting from the physical and emotional stress of continued danger and hardships. The intensity of operational fatigue may vary from minimal reactions to severe emotional disturbances. Minimal reactions are normal to these stresses and are not clinically significant. Operational fatigue is used as a diagnostic term for the following reasons:

(a) The term neurosis or psychoneurosis ordinarily denotes the presence of symptoms which are basically dependent on unconscious conflicts which arose early in childhood.

(b) Operational fatigue is basically dependent on recent situational experiences and conflicts and, as seen at present, has not yet become irreversibly bound to earlier unresolved conflicts over instinctual expressions.

(c) Although there is often a close similarity in the clinical manifestations of operational fatigue and psychoneurosis, the differences mentioned warrant the use of a distinguishing term for those cases which fall in the former category. Later the reactions may spread to and involve earlier residuals and thereby justify the latter diagnosis.

The term "operational fatigue" as used does not denote the existence of an organic factor as a specific agent nor does it implicitly or explicitly deny the basic importance of psychologic conflict in the production of the state designated. Some authorities deny the validity of these reasons for the use of the term "operational fatigue" and feel that organically minded opponents of dynamic psychiatry may use this to deny the essential psychologic origin of the illness as was done by the use of the term "shell shock" in World War I. This truly need not be the case; although there is definitely a factor of fatigue in the production of these states, the exhaustion indeed is an emotional one which is dependent on the situation of living beyond one's psychologic means for long periods of time. Finally the weakened ego has lost the ability to suppress and repress the normal fear reactions. This control mechanism has played itself out. Physical factors play an accessory role but are definitely not the primary ones. At this phase the anxiety responses come in to overwhelm the tired ego and produce the classic syndrome. And so it is believed that there need be no confusion in an essentially dynamic conception of this syndrome because of its designation of operational fatigue.

These cases diagnosed "operational fatigue" after completion of the combat tour, plus the definite psychoneuroses which broke out during the prescribed duty tour, plus the group of acute anxiety states which occurred in normal men on account of the overwhelmingly severe or repeated traumatic experiences in combat, gave the Air Surgeon's Office serious problems of psychiatric care and management some months ago. In order to meet this problem effectively the Army Air Forces has organized a Personnel Distribution Command. The mission of this command is to examine properly, evaluate and care for overseas returnees, excepting the cases of injuries and physical illnesses. This command also supervises and operates the A. A. F.

Officers Replacement Pool and supervises and operates rest camps and convalescent hospitals and centers to which A. A. F. personnel are sent for definitive psychiatric care, convalescence and convalescent training, and subsequent reclassification and reassignment to military duty. It also conducts personnel functions and activities required to effect demobilization of military personnel of the A. A. F.

In order to effect this program, redistribution stations are organized to which overseas returnees are sent for a complete medical and psychiatric examination, so that the effect of the war on these men physically and emotionally is accurately determined. Adequate treatment for the restoration to reasonable health of those men who have been injured by the effects of war is promptly instituted. Discharge or retirement is recommended for those who are too sick to be quickly rehabilitated. For dispositional and treatment procedures, the emotional disorders are diagnosed as operational fatigue and classified as:

(a) Severe. Hospital centers are organized for the definitive psychiatric treatment of cases so diagnosed. These centers utilize all forms of definitive psychiatric care known to be valuable as aids in the recovery and rehabilitation of persons so suffering. These centers will also be used as teaching facilities, as outlined later.

(b) Moderate. Convalescent centers are organized for the care of moderate operational fatigue. Here the unwinding, retraining and rehabilitation of soldiers within the military setting are carried out. This program consists essentially of ego strengthening and supporting procedures rather than definitive psychiatric care. A mental hygiene unit is established at each post so utilized.

(c) Mild. These cases are not of clinical significance. It is felt that the return to duty in a new unit will be adequate to institute the recovery of these men.

The greatest current difficulty in the development of this program is the scarcity of competently trained psychiatric personnel. This handicap has been met by the institution of a comprehensive program of teaching by "training on the job" methods. All efforts should be focused on understanding the clinical and therapeutic angles of the types of psychoneurosis which are arising in the war and are being sent to the zone of the interior for evaluation and treatment. There are four essentials in the success of this program:

1. Organization of combined training-treatment centers as outlined, where the teaching program has available numbers of soldiers with reversible war neuroses. The handling of this clinical material is the basis of the training program.

2. Selection of competent physicians for this training. These men are selected from the group of doctors who are being returned from overseas assignments with fighting units and who, by their war experience, have acquired a definite intellectual hunger for further training and understanding of those problems they have encountered in their front line experience. They must have demonstrated their interest in these problems and certain fundamental capacities for understanding and caring for these types of illnesses. These men are readily selected in one interview by a psychiatrist with experience in teaching post-graduate psychiatry. According to the War Department policy of rotation, numbers of these men are now returning from overseas and will be available for such future training and assignments. These men so selected are sent to the combined training-teaching center, where, under the control of top notch clinical psychiatrists in both the therapeutic and teaching spheres, they receive a course of perhaps eight to ten weeks' intensive instruction in the diagnosis, theory and technics found most useful in the management of these special problems.

3. Assignment to these centers of carefully selected psychiatrists as therapists and teachers. These instructors must have had special training and developed competence for this

particular field of psychiatric endeavor. This is doubly important, as these men must have had enough premilitary clinical psychiatric experience in the care and treatment of the psychoneuroses to reevaluate the old and organize new treatment procedures for this special type of psychiatric problem as current experience shows new technics to be of value. In this manner the most comprehensive and effective therapeutic regimen should be developed.

4. Supervision of these trainees after their assignment to duty as examiners in redistribution stations or as psychiatric assistants in treatment centers, which must be maintained by qualified and experienced psychiatrists. In this way their work will be more effective and a continued training program will be conducted as part of their daily routine.

There are numbers of well qualified psychiatric social workers and clinical psychologists available for utilization in this redistribution and rehabilitation program. These men, classified as Spec. numbers 263 and 289, should be made available readily to take their place in the organization of these centers. In these centers there must be adequate mental hygiene facilities and adequate classification units for proper job classification and placement. A competent Red Cross setup and adequate liaison with the United States Employment Service are essential to the program.

From this discussion it can be seen that the psychiatric program organized for the care of returned overseas soldiers depends essentially on our ability to select and train competent doctors with little or no previous psychiatric training to fulfil the need for junior psychiatric officers in this emergency. The proper selection and training of these men is both the keystone and the cornerstone of the whole program.

The Army Air Forces has found that men who have been overseas and have seen the acute anxiety reactions to battle experiences in statu nascendi have developed, in many cases, a powerfully keen desire for more knowledge and further training in a field of medicine for which their earlier training had poorly prepared them. In one interview it is not a difficult matter to select the doctor who has responded in a positive way to those needs which arose in the heat of the battle situation and who intuitively devised his own technics and ways and means of meeting these situations effectively. With this powerful desire for knowledge and further training, such men have proved to be excellent material for training in psychiatry and take amazing advantage of educational opportunities presented to them. One is agreeably surprised when listening to the high quality of the discussions evoked from a clinical seminar group of these men who have been at work in a hospital as ward clerks with a few hours of lectures and seminars per day for a period of only a few weeks. Such experiences demonstrate that this group is the best available source from which to select those physicians most competent and capable of being trained for the duties essential to the success of the psychiatric program.

Following selection, the nature and type of the training to be given is the next most important consideration. These officers are to be trained on the job. They are brought into the treatment centers as ward assistants and their time, excepting for a few hours daily in lectures and clinical seminars, is spent in the care and treatment of sick people. The teaching program is directed essentially to the clinical aspects of dynamic psychiatry. What these men need to know are the clinical, diagnostic, theoretical and therapeutic aspects of psychoneuroses. In this emergency we must be willing to accept a competence limited to this special angle of psychiatry. We cannot hope to indoctrinate the men

with broader aspects of neurology and psychiatry. These men will have to take care of psychoneuroses which have arisen as a result of the acute stresses of the battle situation. The illnesses which they are called on to manage are essentially dependent on the terrific impact of the environmental stresses on their patients. An understanding of the conflicts so produced and the anxiety reactions to these conflicts, which are the basis of symptom formation, are the matters that these men need to know to be valuable to us in this acute situation. Although it may be desirable to have a knowledge of neuroanatomy, neurophysiology and pathology in the peacetime training of the competent psychiatrist, one must realize that in this crisis we cannot have comprehensively trained psychiatrists in adequate numbers. Such well trained men must be used in the program as teachers, supervisors and consultants to the younger men.

At this time all of our efforts for teaching and training the men who are needed so badly for this special task may well be directed to understanding the elements which are specifically the fundamental and essential ones in the creation of the types of illnesses under consideration. Experienced consultants in psychiatry, with a sound comprehensive training, should always be available to the students for problems which are unusual and for guidance and help in developing competence in meeting routine situations. The principles of training recommended here are ones which one does not like to accept in general postgraduate psychiatric training, but at this time the need for fairly competent men quickly trained for this special job is the all impelling motive. A specialist is seldom competent in his chosen field unless his knowledge rests on a sound base of broad clinical training and experience. That must always be so; but we are not trying to train specialists.

A note may be borrowed at this time from an important experience of the Army Air Forces earlier in the war. At that time literally tens of thousands of mechanics were needed to service the tremendous numbers of fighting planes in foreign theaters. This was indeed a colossal problem in view of the intricacies of these modern fighting monsters. Old time mechanics would wish at least three years to train an apprentice competently in such highly specialized work, but new "on the job" training techniques were devised—new means of hewing closely to the line of the pure essentials needed for the completion of the task at hand. The thousands of planes which rise to the skies in all of our battle fronts throughout the world daily testify to the success of the conception and execution of this training program. The mechanics have met the requirements from that training. They keep the ships flying, and the combat crews keep the bombs dropping. This is a good example of the old adage that the "proof of the pudding is the eating." These men were trained in three months instead of three years.

At this time a leaf may be taken from the book of this experience. Mechanics are not doctors, but we may similarly outline, organize and streamline the teaching program to meet the basic essentials of what a doctor must know to handle these problems and give that knowledge to him directly in the daily routine treatment of the sick. In this way we may produce the necessary number of men sufficiently qualified to handle this problem; men with minimum training, to be sure, but collectively able to produce maximum results in this current emergency.

PSYCHOSOMATIC PROBLEMS

JACK R. EWALT, M.D.

GALVESTON, TEXAS

In the best concept of the term, all human beings are psychosomatic problems. Every patient has both somatic and psychologic problems, excepting those that are dead when the doctor arrives. Draper¹ has stated "If we examine closely the structure of organismic unity which doctors nowadays seem to be striving so hard to preserve for the individual we may find perhaps that its division resides in a contemporary medical attitude and not within the animal at all." Patients in any service show varying degrees of emotional disturbance which alter the course of their illness, and these must be evaluated and treated if optimum conditions for recovery are desired.

Psychosomatic problems may be divided into (1) patients with symptoms referred to one of the body systems but without demonstrable evidence of somatic pathologic change and (2) patients with definite structural alterations thought to be at least in part due to psychologic disturbances.

The patients of the first type, that is, persons with somatic complaints but without observable organic lesions, may in turn be subdivided into two groups. The first of these subtypes is the so-called psychoneuroses, that is the ordinary hysterias, the obsessive ruminative states and the neurasthenias. These patients will usually have a long history of maladjustment, and their neurosis is on such a subtly conditioned basis that management by a skilled psychotherapist is necessary for satisfactory relief of symptoms.

The second subtype consists of the simple anxieties, in which the person responds normally to some immediate environmental situation but in such degree and for so long that changes in physiologic function occur and symptoms are produced.

In these patients reacting to immediate situations with anxiety, the extent and type of symptomatology will vary with the past history and the personality pattern of the individual who is subjected to the environmental stress. One thinks of the person of "coon dog temperament" as showing little response to situations that might cause his "fox terrier" brother untold misery in terms of cold sweats, diarrheas and lost sleep. It is probable, however, that every one has a threshold at which point objectified fears will express themselves as indefinite anxieties, pains and bodily complaints. Into this group fall many of the so-called war neuroses and many of the patients we see in the medical clinics and in the general hospital ward. These individuals, in situations of stress, show an exaggerated response in the autonomic sphere. Noting these sensations, they believe they are ill. Consultation with neighbors or review of the family's medical history often reveals persons suffering from heart disease, cancer or some other illness. The patient, fearing he is similarly afflicted, becomes increasingly concerned over his health; this adds to his burden of worry, increasing his symptoms and giving him more to worry about. We

From the Department of Neuropsychiatry, University of Texas School of Medicine.

Read in a panel discussion on "Neuropsychiatry" in the General Scientific Meetings at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 13, 1944.

1. Draper, G.: *The Concept of Organic Unity and Psychosomatic Medicine*, J. A. M. A. 124:767 (March 18) 1944.

also see "Dr. Built" anxiety of a similar sort. Persons applying for insurance or routine physical examinations may be informed they have "leakage of the heart," anemia or some other condition. The doctor gives such information in his attempt to impress the patient with his skill and thoroughness or to assure himself of an alibi in case the patient falls dead of a coronary attack ten to twenty years later. The patient, having it on good medical authority that he is ill, may begin to dwell on his bodily function to the exclusion of most other interests. In the military setting we see persons subjected to new ways of living, prolonged strain, discomfort or danger developing severe anxiety symptoms with complaints referable to the various body systems. Patients in this group can and should be treated in the general medical clinics. They make up a large, unhappy and misunderstood group of patients who shop from clinic to hospital to the quacks and return. The management of such cases has been discussed elsewhere.²

The second large group of psychosomatic problems comprises those patients with symptoms similar to the anxiety patients but with definite structural lesions in which the psychogenic factors are felt to play an important etiologic role. Studies have been made on peptic ulcer, hypertension, coronary disease, bronchial asthma, mucous colitis and the arthritic disturbances, to mention a few. In considering these disorders two quotations are apt. Nolan Lewis³ has stated "Those who neglect to take into account the psychological factors in disease should be reminded that psychological energy acts through physical structures and produces physical effects, as otherwise phenomena could not appear." And Dunbar⁴ "... at least much too often an etiological relationship between the psychic problem and the illness has been assumed rather than demonstrated."

Many of the studies have been devoted to extensive investigations of the emotional growth and the vicissitudes of the patients suffering from various types of organ dysfunction and pathologic change. Most workers have exercised a laudable caution in ascribing a definite cause and effect relationship to their findings, yet the occurrence of typical psychodynamic configurations in certain types of disorder has led to the suspicion that these influences play an important if not the principal role in the production of the ailment. If this is true, how can psychologic conflicts produce structural alterations in the tissues? From a physiologic point of view the means must be by alterations in autonomic and endocrine functions secondary to psychologic disturbances. Anatomically this means alterations in the cortical and hypothalamic regions, as these areas appear to be the principal central regulators of autonomic function. The second question is Can alterations in autonomic physiology produce pathologic lesions in any organ system? This question may be most logically answered by considering the results of experimental attempts to reproduce certain pathologic lesions by first organic and second psychologic alterations in autonomic functions.

First I will consider ulcerative lesions of the upper gastrointestinal tract. Organic lesions of the central nervous system may produce ulceration of the mucosa of the upper gastrointestinal tract. This has been reported

in human patients by Cushing.⁵ Numerous animal experiments have shown that hypothalamic stimuli or injury frequently produces hemorrhage and erosion of the gastric mucosa. Keller, Hare and D'Amour⁶ produced acute lesions of the gastrointestinal tract by producing intraventricular hemorrhage or by section of the brain at the level of the chiasm. They also produced gastric lesions by hypothalamic lesions in cats. Hoff and Sheehan⁷ produced multiple hemorrhagic erosions of the mucosa of the stomach by lesions involving the tuberal area in monkeys. Keller and D'Amour⁸ report similar findings in the dog and also show that the occurrence of hemorrhage into the mucosa was not prevented by section of the vagus fibers and that ulceration was not prevented if the sympathetic fibers were removed. Watts and Fulton⁹ found that gastric and duodenal ulcerations in monkeys were produced by extensive hypothalamic damage. They explained these lesions as being principally due to ischemia of the mucosa brought about by the vasoconstrictor fibers. These reports have several points in common. Mucosal lesions were very rarely found in the control animals in any series. In the experimental groups the lesions occurred in some of the animals but not in all, even though the central lesion was the same in all animals of a given series. None of the authors offer an explanation for this difference in response to the experimental lesion, although it seems obvious that some factor present in some animals and absent in others, plus the central lesion, was necessary to produce the ulceration.

We thus have abundant evidence in experiments from nature and from the laboratory that central lesions can and do produce structural alterations in the gastrointestinal mucosa of some human beings and some animals. Having established that experimental interference with hypothalamic function is productive of gastrointestinal lesions, we may next consider what role the hypothalamics play in emotional adjustment and the organ participation in our daily living.

The material on this phase of the subject is voluminous. Miller¹⁰ has summarized the literature, stating "It may be asserted that the hypothalamics regulate emotional as well as visceral and somatic manifestations, and all these are frequently concomitant. The conscious awareness that the individual is himself in the throes of emotion implies an activity on the part of the cortex." Miller, in commenting on the corticohypothalamic relationship, says that "... the cortex is to the subcortex as the fine adjustment on a microscope is to the coarse adjustment." Wittkower¹¹ has made a thorough survey of the literature and presents some original data on the influence of emotions on organ function, showing that physiologic processes of many sorts are altered by various emotional states. One of the most conclusive bits of evidence that emotional factors, by altering autonomic function, profoundly influence the development of gastrointestinal ulcerations

is found in the studies of Wolf and Wolff.¹² In a patient with a gastric fistula they observed that emotions of anxiety and hostility produce hypermotility, hyperemia and small areas of hemorrhage in the gastric mucosa. They have demonstrated that these hemorrhagic areas ulcerate readily if exposed to gastric secretion. They have also shown that the small areas of hemorrhage, on exposure to acid secretions, produce more hyperemia and hypermotility. These observations are in keeping with observations that "many peptic ulcer patients show an exaggeratedly aggressive, ambitious and independent attitude. . . ." ¹³ Draper ¹⁴ has studied the incidence of peptic ulcer from several angles. Among many facts he has noted a predominance of aggressive trends, which were found most frequently in males. He also noted certain anthropologic peculiarities in ulcer patients which further emphasize the correlations between physique, psychologic experience and disease. The observations of Spicer and his co-workers ¹⁵ that perforation and hemorrhage from gastrointestinal ulceration increased significantly during the London blitz also suggests the role of emotional states in the cause and course of ulceration of the upper bowel.

Further experimentation similar to that of Wolf and Wolff are indicated. At present we can say that there is abundant evidence to show that autonomic dysfunction, whether organically or emotionally induced, can produce definite alterations in the function and structure of the gastrointestinal system. We have evidence that hostility and anxiety are the emotions productive of such changes and that such characteristics are the ones consistently found in human beings suffering from peptic ulcer as well as those with ulcer-like symptoms but no evidence of mucosal erosion. We also know that the relief of such emotional states favorably influences the course of peptic ulcer and relieves the ulcer-like symptoms of nonulcer patients. Thus the circumstantial evidence becomes rather convincing that ulcers are due to a specific type of emotional reaction in persons of certain constitutional and personality organization. To date we have not produced ulceration by experimentally induced emotional states, unless the German Air Force experiments ¹⁵ over London may be so interpreted.

Hypertension and heart disease are the greatest causes of disability and death in persons past 50 years of age. In our clinic these cases are next in frequency to those with gastrointestinal complaints. An abundant literature is accumulating on the subject, but nowhere do we find the complete answer to the cause or the treatment of this group of disorders. The fact that emotional states may produce profound temporary changes in pulse rate, fainting attacks, blushing and similar vascular phenomena has led to an investigation of the role of psychologic disturbance in the production of hypertensive cardiovascular disorders. Animal experiments have offered some interesting data. Fulton ¹⁶ has shown that faradic stimulation of areas 4 and 6 of the cortex of cats and monkeys will produce a sharp rise in systolic pressure. This effect is abolished by deep general anesthesia or by local anesthesia of the cortex and is reduced by splanchnic nerve section or by destruction of the stellate ganglion. There are many

reports on the role of the hypothalamus in controlling the level of the blood pressure and in the production of experimental hypertension. The reports vary considerably but in general indicate that stimulation of certain portions of the hypothalamus will produce an increase in blood pressure. Miller ¹⁰ has made an excellent survey of the literature on this subject. Allen ¹⁷ has observed interesting differences, in the blood pressure response, to clamping the pedicle of explanted kidneys in dogs. He explains the differences in blood pressure response as being at least in part due to the personality differences or temperament types of the dogs. Thus animal experiments show that the central nervous system by means of the autonomic and hormonal system may influence the blood pressure level. It must be borne in mind, however, that none of these experiments produce in the animal conditions simulating essential hypertension or the cardiovascular syndromes of man and that essential hypertension has been produced experimentally by the Goldblatt preparations. On the other hand, hypertension has been relieved to some extent by the surgical removal of portions of the sympathetic nervous system in man, yet the same operation in Goldblatt's animals produces no lowering of the blood pressure.¹⁸

Many studies have been made of the psychologic functions in patients with cardiovascular disease. Wittkower ²² reports changes in the electrocardiogram and heart size due to strong emotional stimuli and makes an extensive review of the literature on the subject. Merritt ¹⁹ observed inversion of the T wave in the electrocardiogram of patients with "neurocirculatory asthenia." Weiss ²⁰ considers the etiology of essential hypertension to be an interaction of endocrine, autonomic and psychic factors in persons of a particular constitutional pattern. Psychiatrists have made many detailed studies of patients suffering from the cardiovascular diseases and find that they present a distinct behavior pattern. These behavior traits have been very well described by Dunbar,²¹ who has studied this phase of the problem extensively. Alexander ¹³ states that "the hypertensive individual seems to be continuously balanced between an intense nearly conscious but inhibited rage and equally intensive passive dependent wishes." It has been reported ²¹ that treatment directed toward solving the patient's emotional problems in the early phases of hypertension produces a good therapeutic result in many cases. In the late phases of the disorder the amount of relief of the distressing symptoms that may be produced by psychotherapy is approximately as great as that produced by surgical and drug therapy. In the case of the cardiovascular syndromes the evidence that emotional factors play a role in the etiology of these states is suggestive but by no means as definite as in the ulcer cases. In no case have we been able to produce essential hypertension or heart disease in animals or man deliberately by chronic psychologic stimuli.

The other psychosomatic problems could be considered in a similar manner, but the ones discussed serve as illustrations. We thus have two groups of psychosomatic problems: (1) patients without organic

lesions with symptoms due to maladaptation to their environment and (2) patients with organic lesions which may be in part due to maladaptation to their environment. It is possible that the two groups represent different methods of reaction to conflict by constitutionally different persons and not two distinct types of disorder. Much careful experimentation and detailed observation remain to be done.

CONCLUSION

Psychosomatic problems may be divided into two large groups:

I. Patients who react to emotional and environmental stress with bodily complaints and alterations in physiology but without alterations in body structure. These cases are (a) the psychoneuroses and (b) states of simple anxiety.

II. Patients with structural and functional alterations of pathologic proportion in which the emotional reaction to environmental stress appears to play an important role. These problems are still in the experimental phase, but it becomes increasingly evident that emotional factors play some role in all the illnesses of man, and these forces must be evaluated in any study of the cause and treatment of human sickness.

THYROTOXICOSIS TREATED WITH THIOURACIL

WILLIAM S. REVENO, M.D.

DETROIT

Interference with the production of thyroid hormone in animals, first by sulfaguanidine and later by other chemicals, notably thiourea and thiouracil, has been demonstrated by the Mackenzies and McCollum,¹ Richter and Clisby,² Kennedy³ and Astwood and his co-workers.⁴ Observations of this effect in human beings and its application in the treatment of hyperthyroidism were first made by Astwood,⁵ who reported on the clinical use of both thiourea and thiouracil, and later by Williams and Bissell⁶ and by Himsworth,⁷ using thiouracil and thiourea respectively. All reported uniformly good results, but some adverse effects were noted also. Two thiouracil treated patients showed evidence of agranulocytosis,⁸ while 2 more showed pitting edema with some evidence of renal involvement.⁹ Both thiourea⁵ and thiouracil⁹ produced a skin rash in 5 patients. Mild jaundice was noted once.¹⁰

While the total reported number of treated patients has been small and the period of observation relatively

brief, there has been close agreement by all observers that disappearance of toxic symptoms occurs coincidentally with a fall in the basal metabolic rate and a gain in body weight after a latent period of one to several weeks. When the chemical is discontinued all toxic signs return quite promptly. Little or no change takes place in the size of the thyroid, but there may be some softening of the gland. Iodine has no influence on the action of these drugs, but thyroid extract is directly antagonistic.

Experience in the treatment of 9 ambulatory patients with thiouracil¹¹ over a period of eight months is herewith detailed. All had toxic adenomas and 5 had been taking Lugol's solution immediately preceding treatment. All except 2 are still under observation.

REPORT OF CASES

CASE 1.—C. C., a man aged 40, had been under treatment for diabetes mellitus and hyperthyroidism since 1936. Adenoma of the right lobe, with nervousness, tremor, palpitation, weight loss and elevated basal metabolic rate were all present. Diabetes was difficult to control until Lugol's solution was started, when it became stabilized on 20-0-20 units of crystalline insulin daily. Nervousness and weight loss stopped, but the tremor, palpitation, elevated blood pressure and increased pulse pressure continued. The basal metabolic rate in March 1940 was plus 35 per cent, in May 1940 plus 16 per cent, in October 1941 plus 18 per cent and in October 1942 plus 11 per cent.

Lugol's solution was continued until Aug. 7, 1943, when thiouracil 0.8 Gm. daily was started and continued at this level until April 1, 1944, except for two interruptions of eleven and sixteen days each. As may be noted in chart 1, the basal metabolic rate did not fall in the expected manner during this entire period of observation, nor did it rise during the two intervals when the drug was stopped. The body weight and blood cholesterol levels also failed to show appreciable change. Only the tremor and moist palms showed improvement, and the systolic and pulse pressure levels were lower. The diabetes remained under control, and the thyroid gland was unchanged.

All evidence points to a poor response to the drug, and the most that can be said for the effect of thiouracil here is that it performed as well as and no better than Lugol's solution. The prolonged administration of iodine may have been responsible for the poor response, since it has been shown that there is delay of thiouracil action with previous iodine administration.¹²

CASE 2.—L. B., a man aged 64, was first seen in January 1943 because of weakness and exhaustion. There were warm moist palms with tremor, and a nodular bilateral thyroid enlargement, partly substernal. The blood pressure was 120/60 and the weight 169 pounds (77 Kg.). The basal metabolic rate was plus 24 per cent. There was prompt improvement with Lugol's solution, and in four weeks the basal metabolic rate was plus 6 per cent. This treatment was continued until March 31, 1943 and then stopped. The patient was not seen until August 23, when he again complained of a return of his former symptoms. Thiouracil was started on August 24. Chart 2 illustrates the prompt lowering of the basal metabolic rate and the gain in body weight that followed in four weeks. A three weeks interruption in administration of the drug between December 15 and January 10 resulted in a rise of 22 per cent in the basal metabolic rate but an increase in the blood cholesterol level. The figures for this determination are apparently not in accord with the rest of the data and their significance must accordingly be discounted.

The patient continues at his daily work symptom free on 0.4 Gm. of thiouracil daily. The thyroid gland is somewhat larger but softer than it was in the beginning.

CASE 3.—Mrs. R. W., aged 45, had enlargement of the thyroid gland for the past twenty years. She was seen irregularly during this time but presented no evidence of thyrotoxicosis until seven years before I saw her, when she showed a basal metabolic rate of plus 22 per cent. In April 1942 the rate was plus 12 per cent, and a circumscribed firm nodule

Chart 1.—Course with thiouracil in case 1.

was palpated in the right lobe of a uniformly enlarged cystic thyroid gland. Sept. 3, 1943 she first sought help for nervousness, palpitation and tremor, which had appeared three months before along with irregularity in menstruation. Again the thyroid gland showed a bilateral cystic enlargement with a firm nodule in the right lobe. The skin was flushed, there was a fine tremor of the hands and she was obviously restless and disturbed.

Thiouracil was started on September 11, the initial dosage being 0.8 Gm. per day. This was reduced to 0.6 Gm. daily after nineteen days because of epigastric discomfort and pain. As improvement set in and the basal metabolic rate dropped to minus 3 per cent (chart 3) the dosage was further reduced

Chart 2.—Course with thiouracil in case 2.

to 0.4 Gm. daily; but, with a rise in the basal metabolic rate during the next four weeks, 0.6 Gm. was again given daily. She continued symptom free, with little change in the thyroid gland, until March 1, when she noticed an increase in the size of her goiter associated with a choking feeling. This change became more evident during the following four weeks, and the nervousness and tremor returned. No thiouracil was taken for nine days previous to reexamination on March 29.

At this time both lobes of the thyroid showed increase in size, the right more than the left, and there was compression of the trachea with displacement toward the left. Nervousness and palpitation had returned, and the basal metabolic rate was now plus 21 per cent.

Lugol's solution was given and thyroidectomy was performed by Dr. Clark D. Brooks on April 6, 1944. Recovery was uneventful. Examination of the specimen by Dr. Plimm F. Morse disclosed an irregular, lobulated mass of thyroid tissue weighing about 150 Gm., on the external surface of which were many pedunculated nodules hanging from the capsule in a grapelike manner. These nodules were of varying size, some reaching 2 cm. in diameter. On section, many areas of recent hemorrhage and brownish spots due to older hemorrhage were found throughout the structure of the gland. Microscopically the structure was that of a colloid adenoma with large, over-filled, thin walled follicles lined with very flat and compressed epithelium. There were no areas of hyperplasia. In addition to the old and new hemorrhages there were areas of necrosis with beginning organization. No malignant condition was present.

Failure to find hyperplasia, the expected change resulting from thiouracil administration, can be explained only by the fact that no thiouracil had been

Chart 3.—Course with thiouracil in case 3.

taken for seventeen days previous to operation, while iodine had been given for six days preoperatively. The interval for the disappearance of thiouracil hyperplasia does seem short, but it may have been made so by the iodine. The latter effect deserves consideration in view of the established observation that iodine has no influence on the change induced by thiouracil.¹ Astwood² reports that a patient with a large nodular thyroid and a metabolic rate of plus 20 to plus 30 per cent failed to respond to thiouracil. Carcinoma of the thyroid was found, while the remainder of the gland was composed of colloid filled alveoli with uniformly flat epithelium. A certain degree of similarity to the findings just reported may be noted, but the parallelism ends abruptly since our patient showed no evidence of cancer and, for a time at least, responded to the treatment.

Of important significance is the finding of old and new hemorrhage and areas of necrosis in the gland; and while these may have occurred for other reasons, they may also have been caused by thiouracil.

CASE 4.—Miss E. R., aged 76, when first seen in August 1941 was suffering from nervousness, tremor, palpitation, weight loss and ankle edema. There was hypertension (190/90), a hard nodule in the left lobe of the thyroid, auricular fibrillation, tremor and warm moist palms. The basal metabolic rate was

plus 21 per cent. The nervousness and palpitation improved and she gained weight while taking Lugol's solution and digitalis, but she continued to fibrillate, had edema of the lower extremities, and the metabolic rate continued between plus 17 and 35 per cent.

Lugol's solution was stopped Sept. 3, 1943 and thiouracil 0.8 Gm. per day was started September 15. Digitalis was continued. In spite of a reduction in dosage to 0.6 Gm. per day after the first two weeks, improvement proceeded without interruption (chart 4). Digitalis was discontinued after eight weeks and the thiouracil reduced to 0.4 Gm. per day. All evidence of hyperthyroidism has disappeared and there has been no reactivation in spite of two attacks of acute upper respiratory infection. There is no fibrillation and no ankle edema. The thyroid gland is slightly larger but somewhat softer than at first.

This represents a highly satisfactory result obtained in a patient with severe thyrocardiac involvement.

CASE 5.—Mrs. B. C., aged 62, was seen in May 1943 because of dizziness, blurring of vision and exhaustion. There was tremor, moist warm palms, and a palpable adenoma in the right lobe of the thyroid. The basal metabolic rate was plus 38 per cent and the blood cholesterol 150 mg. per hundred cubic centimeters. Some improvement followed administration

of Lugol's solution for a period of four and one-half months. The tremor, exhaustion and elevated metabolic rate continued. The thyroid adenoma remained unchanged.

Thiouracil was started October 1. After ten days the patient developed nausea, chills and fever; the drug was stopped for two days and then reduced from 0.8 to 0.6 Gm. per day. This dose was continued for eight weeks, then increased to 0.8 Gm. per day. There was no ill effect, and a lowering of the basal metabolic rate together with a general improvement followed within two weeks and has continued since then (chart 5). The thyroid adenoma was unchanged except that it felt slightly softer.

CASE 6.—Mrs. G. P., aged 50, complained of being tired, short of breath, and unable to lie down for any length of time. There was an annoying persistent cough, a smothering sensation, palpitation and nervousness. This disturbance had been present for several months previous to January 1943, when she was first seen. Her weight was 191 pounds (87 Kg.), the blood pressure 150/90, the heart enlarged to the left with a systolic murmur at the apex and fibrillation with a pulse deficit of 28. Moist rales were noted at the lung bases, and there was edema of both lower extremities. There was an adenoma of the right thyroid lobe, and the basal metabolic rate was plus 24 per cent with a blood cholesterol level of 136 mg. per hundred cubic centimeters. She improved while taking Lugol's solution and digitalis and following a reduction

diet but tired of this regimen after three months and stopped all medication. In June her weight was down to 167 pounds (76 Kg.), all her previous symptoms had returned, and again there was a pulse deficit with the auricular fibrillation. Lugol's solution and digitalis were prescribed but not taken. She returned in November in much the same condition and this time was started on digitalis and 0.6 Gm. of thiouracil per day.

The response was both prompt and satisfactory subjectively and objectively (chart 6). The pulse deficit had disappeared and the digitalis was discontinued five weeks after the beginning of treatment. From about the eighth week on however the patient showed evidence of failure to follow the treatment, and the subsequent observations are accordingly of little value.

CASE 7.—A. S., a man aged 67, appeared in November 1943 complaining of epigastric discomfort caused by reactivation of a duodenal ulcer. Attacks had occurred several times in the past two years. In addition to the evidence of duodenal ulcer, both lobes of the thyroid were palpable, with a small adenoma in the right lobe, and there was a tremor of the hands, with warm moist palms. The basal metabolic rate was plus 9 per cent. Thiouracil 0.6 Gm. per day was started November 22 and continued to the present except for two intervals, one

of one week when he developed an acute upper respiratory infection and one of two weeks when he developed recurrence of severe epigastric pain.

While the response in this patient has been quite satisfactory the reactivation of ulcer symptoms while taking the thiouracil may have resulted either from

local irritation or from pituitary stimulation by the drug. Whichever is true, care certainly should be exercised in the administration of thiouracil to patients with peptic ulcer.

CASE 8.—Mrs. E. L., aged 82, complained of choking and tightening of the throat, dry cough, nervousness, insomnia and hypertension of long standing when she first appeared in January 1944. There was nodular enlargement of both lobes of the thyroid. The palms were warm and moist and there was a fine tremor. Lid lag and a definite "stare" were present. The pulse was rapid. The blood pressure was 220/120.

Thiouracil 0.6 Gm. daily was started January 24, before a basal metabolic rate determination was made. The only difficulty encountered in taking the drug was an initial gastric distress. Subjective improvement, such as decrease in cough and constriction of the throat, with lessening of tremor appeared within three weeks after starting treatment. By the time of the last visit, when the basal metabolic rate was minus 3 per cent, the pulse rate, nervousness, tremor and eye signs had subsided manifestly (chart 7).

CASE 9.—Mrs. S. A., aged 58, when seen Aug. 17, 1943, complained of weakness, palpitation, tremor and profuse perspiration of two years' duration. She had had a goiter since the age of 18. There was enlargement of the right thyroid lobe, the skin was moist and flushed and the blood pressure was 144/90. There was no tachycardia.

Chart 7.—Course with thiouracil in case 8.

The patient has not appeared for further observation, so that no conclusion can be drawn as to the effectiveness of the treatment.

COMMENT

In reviewing the treatment of these 9 patients the following points are worth noting:

1. *Dosage.*—The initial dose was either 0.6 or 0.8 Gm. daily. This was eventually reduced to 0.4 Gm. daily in cases 2 and 4; it was maintained at 0.6 Gm. daily in cases 3, 6, 7, 8 and 9 and was kept at 0.8 Gm. in cases 1 and 5. Tablets of 0.2 Gm. each were administered either two, three or four times daily.

2. *Reactions.*—Gastric distress in the form of pain, burning and gnawing was noted at the onset of treatment in cases 2, 3, 7, 8 and 9. This was promptly controlled by the taking of food along with the medication. Patient 6 reported nausea with chills and fever ten days after starting treatment. This lasted two days, during which the drug was stopped. No further reaction followed resumption of treatment. Opportunity for determining whether agranulocytosis had occurred was not available, since the patient was out of the city at the time of the reaction.

No instances of urticarial or toxic skin rash, agranulocytosis, anemia, edema or jaundice occurred.

The rapid enlargement of the thyroid in case 3, with increase in toxicity and evidence of recent and old hemorrhage in the gland, deserves mention as a possible effect of the drug.

3. *Elapsed Time Before Improvement.*—Excepting for case 1, in which no noteworthy effect resulted, the latent interval was two weeks in cases 6, 7 and 9, four weeks in case 2, six weeks in case 4, eight weeks in case 3, ten weeks in case 8 and fourteen weeks in case 5. The long interval in the last instance was undoubtedly due to too low a dosage of thiouracil.

4. *Changes in the Thyroid.*—No significant change was noted in the appearance of the gland except a slight softening in every case except in case 3, in which rapid enlargement developed.

5. *Blood Cholesterol Levels.*—No reliance could be placed on the results of these determinations, since the figures failed to rise or fall with decrease or increase, respectively, in basal metabolic rate determinations. Perhaps this is due to the fact that all patients in this series had toxic adenomas, a condition in which the inverse relationship between cholesterol level and basal metabolic rate is not as distinct as it is in toxic diffuse goiter.

6. *Previous Medication with Iodine.*—Five patients had been treated with iodine before thiouracil was given. With the exception of patient 1, all responded favorably to the treatment. It is possible that patient 1 failed to respond because of prolonged administration of iodine (six years).

CONCLUSIONS

Of 9 patients treated with thiouracil, 6 showed satisfactory results characterized by cessation of disturbing symptoms, fall in basal metabolic rate and gain in weight. Two of these patients had anricular fibrillation; in 1 of these the use of digitalis was discontinued after eight weeks; the other showed promise of improvement, which failed to materialize because of lack of cooperation.

One patient in whom diabetes mellitus coexisted, and who had been taking iodine for six years, failed to respond to therapy.

Another patient responded favorably at first but developed rapid enlargement of and hemorrhage into the gland and was subjected to surgery.

The third failure was of a patient who, while showing some clinical improvement, failed to show a drop in basal metabolic rate during the short period she was under observation.

The results in the responsive patients appeared as good as those following successful thyroidectomy.

Most Eminent Authority on Surgery During the Middle Ages.—Guy de Chauliac (1300-1368) was the most eminent authority on surgery during the Middle Ages. His *Chirurgia magna* was written in 1363. Born in the countryside near Auvergne in France, he took holy orders and was educated in medicine at Toulouse, Montpellier and Paris, with a special course in anatomy at Bologna. He settled in Avignon and was surgeon to the French popes. He operated for hernia and cataract but hesitated to cut for the stone. He employed the cautery for cancer. He treated ulcers by investing them with a collar of steel. His discussion of fractures and dislocations is good. He used Theodoric's narcotic or soporific inhalant as an anesthetic. He did not believe in the power of nature in healing wounds, but in the surgeon's intervention with salves, plasters, etc.—Clendening, Logan: *Source Book of Medical History*, New York, Paul B. Hoeber, Inc., 1942.

THE TREATMENT OF SULFONAMIDE
RESISTANT GONORRHEA WITH
PENICILLIN SODIUM

RESULTS IN 1,686 CASES

LIEUTENANT COLONEL THOMAS H. STERNBERG
AND

COLONEL THOMAS B. TURNER

MEDICAL CORPS, ARMY OF THE UNITED STATES

In May 1943, soon after preliminary evidence of the effectiveness of penicillin in the treatment of gonorrhea was obtained by Mahoney and his co-workers¹ and Herrell, Cook and Thompson,² studies were inaugurated by the Surgeon General's Office of the U. S. Army with a view to determining as rapidly as possible time-dosage factors in the penicillin treatment of this disease. The clinical trials were carried out in fifteen selected army hospitals. Altogether, 1,686 patients with sulfonamide resistant gonorrhea were studied.

METHOD OF STUDY

The hospitals participating in the study and the responsible investigators in each are shown in table 1. Similar requirements as to the selection of patients, methods of treatment and criteria of cure obtained in each.

Selection of Patients.—Patients admitted to the study were limited to those fulfilling the following conditions:

1. A clear history of gonorrhea acquired within the past few weeks or months.
2. Typical clinical signs and symptoms of gonorrhea at the time penicillin treatment was begun.
3. Smear and culture positive for gonococci immediately prior to penicillin therapy.
4. Sulfonamide resistant gonorrhea as determined by failure to respond to two or more courses of sulfathiazole or sulfadiazine, each course consisting of at least 20 Gm. of drug administered within a period of five days.

Plan of Treatment.—No patient was started on penicillin treatment until at least five days after the discontinuance of other medications, including sulfonamides. Solutions of penicillin in sterile saline solution or distilled water were prepared daily from the dried powder and were refrigerated at approximately 4 C. when not in use. The individual dose in all cases was either 10,000 or 20,000 Oxford units injected intramuscularly at intervals of three hours, day and night.

As originally projected this study called for the treatment of four groups of patients employing respectively a total dosage of 40,000, 80,000, 120,000 and 160,000 Oxford units, with each group further divided according to whether the individual dose was 10,000 or 20,000 units. The interval of three hours between doses remained constant for all groups.

Later, when it was apparent that favorable results were being obtained with all dosage schedules, two new groups were added, one employing a total dosage of 50,000 units and another employing 100,000. The latter

dosage levels were selected largely because of convenience, arising from the fact that the drug was commonly delivered in ampules containing 100,000 units.

It should be emphasized that no other medication and no local treatment whatever were given concurrently with penicillin or during the observation period.

Criteria of Cure.—Patients included in this study were routinely retained in the hospital for at least twenty-one days following the completion of penicillin therapy. During this period the following examinations were performed:

1. Daily examination for evidence of urethral discharge.
2. Daily two glass urine examination.
3. Cultures and smears for gonococci within forty-eight hours after the completion of treatment, and on the seventh, fourteenth and twenty-first days. These bacteriologic studies were made on material obtained from the urethra as long as such material was available. If no urethral discharge was present, cultures and smears were made on prostatic secretion expressed through prostatic massage. The prostatic secretion was examined either directly or after collection in urinary sediment.

Fort Benning.....	Major C. G. Stillinger, Major R. F. Kelsey

Patients were termed "cured" and released from the hospital if they were asymptomatic and bacteriologically negative on the twenty-first day after completion of treatment. As indicated later, the vast majority of patients became clinically and bacteriologically negative within the first week. "Failure" was determined by the presence of positive smears or cultures on the seventh post-treatment day or at any time thereafter, even though the patient had no urethral discharge. Because of the wide geographic dispersal of patients on release from the hospital, no attempt was made to obtain follow-up examinations beyond the period of hospitalization.

MATERIAL STUDIED

A total of 1,686 patients with sulfonamide resistant gonorrhea were included in the study. All were men between the ages of 18 and 38 years, the mean age being 23. The average duration of infection was fifty-one days. The average amount of sulfonamide drug received prior to penicillin therapy was 58 Gm. Most of the patients included in the study had received some form of local treatment subsequent to sulfonamide therapy. In addition, 236 patients had been treated unsuccessfully with hyperpyrexia, induced either mechanically or by means of typhoid vaccine.

RESULT OF TREATMENT

Results According to Total Dose.—In table 2 are shown the results of treatment with one course of penicillin, according to the total dose administered. It is evident that remarkably satisfactory results were obtained with all dosage schedules employed. In the first series of patients treated no important differences

TABLE 2.—Results of Treatment According to Dose of Penicillin (One Course Only)

Total Dose Penicillin	Number Treated	Failures	Per Cent Cured
160,000.....	144	3	97.9
120,000.....	191	9	95.3
80,000.....	225	10	95.6
40,000.....	137	12	91.2
100,000.....	433	15	96.5
50,000.....	556	77	86.2
Total.....	1,686	126	92.5

in the final result were noted among the groups treated with 40,000, 80,000, 120,000 and 160,000 units respectively.

When larger series were compared employing a total dose of 100,000 units for the one and 50,000 for the other, the results were significantly poorer with the smaller dose.

It should be pointed out that the dosage schedules used are only approximate, since at the time of these studies potency assays were crude and subject to as much as 25 per cent error in either direction in some instances. Furthermore, batches of the drug were shipped to the various hospitals all over the country and it is believed that in some instances, at least, conditions of shipment such as exposure to excessive heat may have resulted in a loss of potency. It was definitely noted that in certain hospitals using particular lots of penicillin the results were inferior to those of groups treated with the same dosage schedule elsewhere. This was particularly noticeable in the 50,000 unit group, since here the dosage was probably on the borderline of effectiveness and any loss of potency became evident by an appreciable increase in the percentage of failures. In two hospitals certain lots of the drug resulted in a 50 per cent failure rate at the 50,000 unit schedule of treatment. In the same hospitals using the same dosage schedule but with penicillin of different manufacture, the results were similar to those obtained elsewhere. On the other hand, the 91 per cent cure rate obtained in the 137 cases treated with 40,000 units of penicillin may have been due to the use of underassayed drug.

Effect of Size of Individual Dose.—No significant differences in the final results were noted when a given total dose was administered in individual injections of 10,000 or 20,000 units. For example, employing a total dose of 100,000 units, of 261 patients treated with five injections of 20,000 units each, favorable results were obtained in 96.6 per cent, while of 172 patients treated with 10 doses of 10,000 each, exactly the same percentage responded favorably (table 3).

These observations are of very practical importance from a military and probably a civilian standpoint. When the total amount of drug is administered in five doses at three hour intervals treatment is accomplished within a total period of twelve hours, while with ten

doses at the same interval treatment must extend without interruption through the night. In situations in which hospitals are understaffed or blackout precautions must be observed, it is advantageous to complete treatment during the daylight hours and largely during the normal working day.

Response to Treatment in General.—The response to treatment was ordinarily dramatic, with prompt disappearance of symptoms and reversal of cultures and smears to negative. The average time for the urethral discharge to disappear or change from purulent to mucoid was two days, although in the majority of cases both objective and subjective improvement was noted within a few hours after the beginning of treatment.

In patients responding to treatment, cultures were almost invariably negative within forty-eight hours, although smears taken within this period occasionally showed degenerated coccoid organisms. Smears of this type were rarely noted after forty-eight hours.

In roughly 20 per cent of the patients a slight intermittent mucoid discharge persisted from one to three weeks, gradually resolving over this period. At first it was thought that this indicated failure of therapy; however, since careful study commonly failed to reveal the presence of gonococci and this slight discharge eventually ceased spontaneously, it is now regarded as a normal finding incidental to the healing process.

Analysis of Failures.—Of the 1,686 patients treated, 126 failed to respond to one course of penicillin. Of these failures 84 became manifest by the end of the first treatment week, 31 during the second and 11 during the third. For the most part the 84 failures during the first post-treatment week were those patients receiving the lower total dosages of penicillin. In these cases the clinical response was not conspicuous. Moreover, while twenty-four to forty-eight hour cultures were usually negative, possibly because of the presence of excreted penicillin, the smears frequently remained positive and cultures became positive within a few days

TABLE 3.—Results of Treatment (Effects of Size of Individual Dose and Length of Treatment)

Total Dose	Size of Individual Dose	Length of Treatment, Hours	Number Treated	Number of Failures	Per Cent Cured
120,000.....	20,000	15	105	3	97.1
100,000.....	20,000	12	261	9	96.6
80,000.....	20,000	9	121	8	93.6
Total.....			487	20	95.9
120,000.....	10,000	23	86	6	93.0
100,000.....	10,000	27	172	6	96.5
80,000.....	10,000	21	101	2	98.0
Total.....			359	14	96.1

thereafter. The majority of the 31 failures which became manifest during the second post-treatment week responded temporarily to treatment and then relapsed both clinically and bacteriologically. Of the 11 failures appearing in the third post-treatment week, 6 were completely asymptomatic and were judged failures on the basis of bacteriologic evidence. Since these 6 patients were promptly and successfully retreated with penicillin, it is not known whether spontaneous bacteriologic cure would have resulted without the second course of penicillin.

Influence of Duration of Infection.—In 1,154 patients of this series the onset of gonorrhea was less than sixty days prior to the initiation of penicillin therapy, and in 532 infection had been present for longer than sixty days. A successful outcome was observed in 92 per cent of the one group and in 93 per cent of the other, indicating that duration of infection is not an influential factor in determining the response to penicillin therapy.

Influence of Previous Fever Therapy.—In addition to at least two courses of sulfonamides, 236 patients had been subjected to artificially induced hyperpyrexia for sulfonamide resistant gonorrhea. Of these 92.2 per cent responded to one course of penicillin, as compared with a response rate of 92.7 per cent for those who had not had previous fever therapy.

Influence of Race.—Of 139 Negro patients in the entire series of 1,686, 125, or 90 per cent, responded favorably to one course of penicillin, as compared with a favorable response of 92.8 per cent in the white group. This small difference in the results in the two groups is not considered significant.

Response of Patients with Complications.—In general it can be said that the complications of gonorrhea responded well to treatment with penicillin. In most instances improvement began shortly after the penicillin was administered and continued until the patient was well. Of 47 patients with acute epididymitis at the time penicillin therapy was initiated, 43 responded to one course and 4 required a second course. Of 14 patients with severe acute prostatitis 13 responded immediately, while the additional case responded to a second course of penicillin.

Included in this series of patients were 9 who had mild to moderately severe articular involvement associated with a persistent gonococcal urethritis. Presumably the joint lesions were gonococcal in origin. Of these 9 cases 3 responded to one course of penicillin and 2 to an additional course. In 4 cases there was no substantial improvement to two courses of penicillin, although the coexisting urethritis responded satisfactorily.

Not included in this series are 5 patients with sulfonamide resistant gonorrhea and severe acute arthritis, presumably gonococcal in origin, who, because of the severity of the disease, were given considerably larger doses of penicillin. The results were excellent in each case. Among the complications of gonorrhea observed was 1 case of gonococcal conjunctivitis, proved by culture, which responded to 160,000 units, and a case of keratoderma blennorrhagicum, which responded to 120,000 units.

Retreatment of Failures.—Of the total of 126 failures to one course of penicillin 85 were retreated, a total dose of 100,000 units being used in each. Of these, 78, or 91.8 per cent, were cured. In 4 of the 7 cases which failed to respond, a third course of 100,000 units of penicillin was given, with a satisfactory outcome in all. No true instance of penicillin resistance was observed.

Reactions to Treatment.—No serious reaction to penicillin treatment was observed. In 98 patients soreness at the site of injection was noted, but 42 of these patients were in a group of 50 who were treated with one lot of the drug. Other reactions listed were mild fever in 7, slight nausea in 5, headache in 4, chilliness in 4 and dizziness in 3. However, since the conditions

of the study required that all untoward signs or symptoms occurring during or immediately after penicillin treatment be recorded, it is probable that in many instances the symptoms noted were coincidental and not true reactions to the drug.

COMMENT

It is evident from the foregoing results that penicillin is remarkably effective in the treatment of gonorrhea. Doses totaling more than 80,000 to 100,000 units appear to offer little advantage over these amounts, and, indeed, the results obtained with 40,000 and 50,000 units are sufficiently good to warrant the use of these total doses when supplies of the drug are limited.

It is quite possible that somewhat better results might be obtained by varying the time-dosage relationship. Perhaps a two hour interval between doses would be more effective than the three hour interval employed in these studies. Likewise, larger initial doses followed by smaller doses might offer advantages over the schemes described here, but these variations appear to be questions of detail rather than ones of major importance.

In this series of cases, penicillin was administered by the intramuscular route, which on the basis of studies by Rammelkamp and Keefer³ appears to be superior for this purpose to intravenous administration. The practical advantages of intramuscular over intravenous administration are obvious. In order further to simplify the mechanics of treatment a practicable method of prolonging absorption and excretion of penicillin is needed. In this connection experiments are now in progress employing penicillin incorporated in oil vehicles in the hope that satisfactory results may be obtained by the administration of one or two large doses of penicillin.

While at the very onset of these studies it was evident that penicillin was greatly superior to the sulfonamides in the treatment of gonorrhea, it was nevertheless expected that a proportion of cases treated would prove to be resistant. This expectation of penicillin resistance failed to materialize, since all patients in this series subjected to three courses of treatment responded favorably. Furthermore, of the many thousands of soldiers treated for gonorrhea with penicillin during the past six months, instances of penicillin resistance have been extremely rare. The recent report of Cohn and Seijo⁴ tends to confirm this observation, since in their *in vitro* experiments penicillin concentrations of 1 to 10,000 killed all gonococcus strains tested.

The ability of the gonococcus to develop resistance to penicillin through initial exposure to small concentrations of the drug is still undetermined. The evidence afforded by this series indicates that this happens rarely, if at all, since 92 per cent of failures to the first course of treatment responded to a second course. Furthermore, of the 77 cases which failed following initial therapy with the small first course of 50,000 units of penicillin, 57 were retreated with a 100,000 unit schedule, of which 52, or 91.2 per cent, responded favorably. Of the 5 failures to the second course, 3 were given a third course of similar dosage, with satisfactory results in all.

The possibility of penicillin treatment of gonorrhea masking or delaying the appearance of manifestations

of early syphilis must be borne in mind. While most of the patients in this series were beyond the incubation period of primary syphilis, several cases were observed in which it is possible that penicillin affected the development of early syphilis. The most definite instance was that of a patient with a small ulcer at the frenum, to whom 100,000 units of penicillin was administered before the lesion was studied by dark field examination. The dark field examination was negative the day following and the lesion healed rapidly. Six weeks later a typical dark field positive chancre appeared in the same location. The patient denied further sexual exposure. Because of the known effect of penicillin on *Treponema pallidum*, patients receiving penicillin therapy for gonorrhea should be observed clinically and serologically for evidence of syphilis for a period of at least three months.

SUMMARY AND CONCLUSIONS

Studies have been carried out in fifteen selected army hospitals with a view toward determining as rapidly as possible time-dosage factors in the treatment of sulfonamide resistant gonorrhea with penicillin. A total of 1,686 patients refractory to at least two courses of a sulfonamide and in some cases to artificially induced fever were treated with total dosages varying from 40,000 to 160,000 Oxford units per case, the individual dose being 10,000 or 20,000 units intramuscularly every three hours.

These studies showed penicillin to be a remarkably effective drug in the treatment of gonorrhea, usually causing disappearance of symptoms and reversal of bacteriologic findings within forty-eight hours. One course of treatment with a dosage of 160,000 units per case effected cures in 98 per cent, 80,000 to 120,000 units in 96 per cent and 50,000 units in 86 per cent. No significant differences in the final results were noted when a given total dose was administered in individual injections of either 10,000 or 20,000 units. Furthermore, little advantage was gained by prolonging the time of treatment schedules beyond twelve hours.

Factors such as duration of infection, previous fever therapy and race appeared to have no effect on the results of therapy.

Of the total of 126 failures to one course of penicillin, 85 were retreated, using a 100,000 unit dosage. Of these, 78, or 91.8 per cent, were cured. Thus, by retreatment of failures with a second course, 99 per cent cures were obtained. No case in the entire series proved to be penicillin resistant.

Complications of gonorrhea responded well to penicillin, although the more serious forms of complications required prolonged treatment with higher dosage.

Reactions to penicillin were inconsequential, and in no instance was it necessary to discontinue treatment for this reason.

Because of the known effects of penicillin on *Treponema pallidum*, the possibility of masking or delaying the development of early syphilis must be considered.

Finally, it should be recognized that the treatment of gonorrhea has been completely revolutionized in the past few years, first by the introduction of the sulfonamides and, more recently, by the development of penicillin. It is clear that the management of gonorrhea now belongs within the sphere of the chemotherapist, and that local treatment is rarely necessary and may do more harm than good.

ABSTRACT OF DISCUSSION

LIEUTENANT COLONEL IRVING S. WRIGHT, M. C., A. U. S. This compilation of important data represents an encouraging example of cooperation in clinical research. This should encourage others to embark on similar studies when maximum data are needed in the shortest space of time. A few comments based on experiences at the Army and Navy General Hospitals and at many hospitals later visited may prove of interest. In some patients, both male and female, the cultures became negative within four to six hours after the initial dose. Certain of these patients had had profuse discharges, with positive culture for six months or more. The possibility that the excretion of penicillin in the discharge is a factor in inhibiting the culture growth must be considered. Two patients, both men, had had profuse discharges for months. Smears from each were positive in the usual sense of interpretation; that is, many gram-negative intracellular diplococci, which could not be differentiated from gonococci, were found. Cultures failed to grow the organism. One of these patients had twenty-seven negative cultures in a laboratory that grew practically 100 per cent positive cultures in the remainder of the gonorrhea patients. These 2 patients were treated with five and eight courses of sulfonamides respectively, with hyperthermia and with two courses of penicillin of 100,000 units each. This therapy had absolutely no effect on the discharge or on the organisms seen in the smears. The findings suggest that the organism may not be a true gonococcus, but that is as far as we are able to go. I should like to ask Colonel Turner whether he knows of other examples of this group. We have tried penicillin in the treatment of rheumatoid arthritis which arose during the acute phase of gonorrhea and continued after the discharge had ceased. The etiologic classification of these cases is difficult. They differ from the so-called acute gonorrheal arthritis reported in the paper under discussion. The treatment of patients with typical rheumatoid arthritis has been disappointing in our hands. The broader implications arising from the findings of this and similar studies cannot be overestimated. Once more the scientific approach is leading the way, but the problems of its application must be carefully considered. This is easy for members of the armed forces and relatively easy for the professional prostitute. Today, however, our great source of infection is from the amateur pick-up, the girl who comes from a surprising cross section of our population. The widespread use of penicillin in this group must be the result of careful but intense educational programs. A note of caution must be raised, however, against the widespread increase of promiscuity which may arise, with its resultant serious dislocations to our social structure.

DR. JOHN F. MAHONEY, U. S. P. H. S.: It would be an error not to call attention again to the point that the use of penicillin in the treatment of gonorrhea may have the effect of masking or greatly altering the symptoms of the invasion of a concomitantly acquired syphilis. As the product becomes more generally available and more generally used, an increasing number of instances of faulty and delayed recognition of the latter disease probably will be encountered. Repeated serologic tests for syphilis for at least two months following treatment appears to offer the best safeguard, and this feature may well become an important part of follow-up work. In much of the early work with penicillin, investigators have been faced with the necessity of working with limited amounts of the product. This has called forth efforts to refine the dosage to a point where the utmost in results would be produced by each unit available. In the future, and especially if the material becomes as plentiful as now appears certain, the concept that "the dangerous dose is the small dose" will probably gain adherents. The objective will then be to use a sufficient amount of the drug to produce a clinical response as rapidly as possible. In view of the nontoxic character of the substance, the utilization of larger amounts may be accomplished without an appreciable risk of producing untoward symptoms. The questions of total dosage, the duration of treatment, the interval between injections and the number of injections cannot be considered as established at the present even in the light of the favorable results which have been recorded in the present report. Products of greater potency and the development of preparations which are absorbed and excreted less rapidly may have the effect of permitting to a

ment schedules to be utilized which are less burdensome and as effective as those in use at the present. The impact of the therapy on incidence of gonorrhea and especially on the public health approach to the disease forms an interesting field of speculation. Should the experiences of the future confirm the impressions which are inescapable on the basis of the material at hand, then surely control of the disease through the medium of the venereal disease clinic will require reorientation. A different type of facility may be needed to implement the new therapy. That gonorrhea may cease to be of major public health importance in the none too distant future seems to be an entirely reasonable assumption.

LIEUTENANT COLONEL THOMAS H. STERNBERG, M. C., A. U. S.: The existence or development of penicillin resistant cases of gonorrhea has been a possibility of great interest and of some concern to the Army. In the data presented by Colonel Turner it is of interest that no true instance of penicillin resistant gonorrhea was encountered, provided three courses of penicillin were administered. Since the termination of these studies, many thousands of individuals with gonorrhea have been treated with penicillin in various army hospitals, and particular efforts have been made to uncover cases not responding to adequate penicillin therapy. While such cases are not infrequently reported, investigation reveals that usually they have been labeled as penicillin resistant on the basis of either inadequate penicillin treatment or persistence of a mucoid discharge, which is bacteriologically negative and later proves to be nongonococcal in origin. I have just completed an extensive trip throughout the southwestern portion of the country, visiting numerous army hospitals routinely using penicillin in the treatment of gonorrhea. During these visits the relatively few instances of so-called penicillin resistant gonorrhea were investigated. In most instances the total dosage of penicillin did not exceed 200,000 units, and in no case was it possible to isolate a strain of gonococcus which was resistant *in vitro* to the more concentrated dilutions of penicillin. To date the army experience indicates that the incidence of truly penicillin resistant gonorrhea is at least unusual and further suggests that the term penicillin resistant gonorrhea should be applied cautiously and only after failure to respond to comparatively large doses of penicillin as determined by adequate clinical and laboratory studies.

DR. ALFRED COHN, New York: May I report the essential findings of a study on penicillin therapy in 100 women and 20 men who suffered from sulfonamide resistant gonococcal infections. This study is still in progress in collaborations with my associates Dr. Boris A. Kornblith and Dr. Isaak Grunstein. The 100 women were hospitalized for penicillin treatment at the gynecologic service of Dr. Howard C. Taylor Jr. at Bellevue Hospital. Our studies were directed first toward evaluating the optimal total dosage and second to determine an adequate time schedule for cure. The results of administering various amounts of penicillin in the female group point to the fact that a minimum total dosage of 100,000 Oxford units intramuscularly is both necessary and sufficient for bacteriologic cure. The time schedule that was found to be most satisfactory without failure averaged between six and nine hours. The penicillin was administered either in four intramuscular injections of 25,000 units each or by an initial injection of 50,000 units followed by two injections of 25,000 units each. Twenty ambulatory men who suffered for a number of months from sulfonamide resistant gonococcal infections with chronic complications, 18 with prostatitis and 2 with epididymitis, were treated at the Central Clinic of the Department of Health, City of New York. A total dosage of 100,000 Oxford units of penicillin was administered intramuscularly to all 20 patients. Two schedules of therapy were employed: 1. An initial injection of 50,000 units was followed by two subsequent injections of 25,000 units each at three hour intervals; total time of therapy, six hours. 2. An initial injection of 40,000 units was followed by two subsequent injections of 30,000 units each at two hour intervals; total time of therapy, four hours. Thus far no failure of therapy has been encountered in any of these 20 patients who have been followed up by repeated urethral and prostatic smears and cultures over a period of between two and four weeks. Urethral cultures taken at one hour intervals

after the initial injection of penicillin became negative between the third and fourth hour after treatment was initiated. Smears of urethral discharges showed involution and disintegration of the gonococci and leukocytes by the end of five hours in most cases. Our findings indicate that an adequate minimal dosage of 100,000 units of penicillin administered over a period of from four to six hours to ambulatory patients is a satisfactory routine in the treatment of sulfonamide resistant gonococcal infection.

COLONEL THOMAS B. TURNER, M. C., A. U. S.: In reply to Colonel Wright's question about observing the organisms which do not grow out on culture, we have observed a similar thing in our hospitals. We assume that it is due to the presence of penicillin and that they do not grow out.

PENICILLIN FOR THE TREATMENT OF CHEMORESISTANT GONORRHEA IN THE FEMALE

ROBERT B. GREENBLATT, M.D.

Surgeon (R) U. S. Public Health Service

AND

ANITA R. STREET

Laboratory Director, Southeastern Medical Center, Oakland Island

SAVANNAH, GA.

With the advent of the sulfonamides the eradication of gonorrhea from the human race seemed quite likely. The promise contained in the earlier reports for the treatment of gonorrhea with sulfonamides, however, has not been completely fulfilled. Moreover, the therapeutic results for the female have not been so good as for the male, because of vagaries in her anatomic makeup. The physiologic mucoid alkaline secretions of the cervix aid and abet the growth of the gonococcus; the anatomic arbor-like arrangement of the cervical glands conceal this micro-organism in protective depots for survival. Even against such odds the sulfonamides brought under control a very large number of women with acute and chronic gonorrhea. The exceptions were the females who harbored resistant strains or in whom, because of chronicity of long duration, the gonococcus had taken tenacious hold in the subepithelial layers of the mucosa lining Skene's ducts, Bartholin's glands, the endocervix or the fallopian tubes. Chronicity and chemoresistant strains proved a barrier that sulfonamides frequently failed to overcome.

The early reports of 85 per cent cures of gonorrhea with sulfonamides no longer hold, for the persistence of certain strains which have gradually permeated a selected stratum of the populace has reduced the effectiveness of sulfonamides to little better than 55 per cent. It is further true that improved bacteriologic technics have helped to uncover many carriers of gonococci in spite of complete absence of clinical signs and symptoms.¹ The sign on the door, namely a purulent urethral discharge, is not a worthy criterion on which to base a clinical diagnosis of gonorrheal infection. Too frequently, particularly in the old infected case, is it lacking. Too frequently, in spite of a frank urethral discharge, gonococci are not to be found and other organisms, among them the trichomonad, are common offenders.

Pelouze, the prophet of doom in the sulfonamide wilderness, was haunted by the specter of the carrier and the chemoresistant strain. He continually exhorted medical authorities to beware of the false security into which we have been lulled by sulfonamides. Shall we

1. Koch, R. A.; Mathis, E. N., and Geiger, J. C.: Ven. Dis. Inform. 25: 35, 1944.

of early syphilis must be borne in mind. While most of the patients in this series were beyond the incubation period of primary syphilis, several cases were observed in which it is possible that penicillin affected the development of early syphilis. The most definite instance was that of a patient with a small ulcer at the frenum, to whom 100,000 units of penicillin was administered before the lesion was studied by dark field examination. The dark field examination was negative the day following and the lesion healed rapidly. Six weeks later a typical dark field positive chancre appeared in the same location. The patient denied further sexual exposure. Because of the known effect of penicillin on *Treponema pallidum*, patients receiving penicillin therapy for gonorrhea should be observed clinically and serologically for evidence of syphilis for a period of at least three months.

SUMMARY AND CONCLUSIONS

Studies have been carried out in fifteen selected army hospitals with a view toward determining as rapidly as possible time-dosage factors in the treatment of sulfonamide resistant gonorrhea with penicillin. A total of 1,686 patients refractory to at least two courses of a sulfonamide and in some cases to artificially induced fever were treated with total dosages varying from 40,000 to 160,000 Oxford units per case, the individual dose being 10,000 or 20,000 units intramuscularly every three hours.

These studies showed penicillin to be a remarkably effective drug in the treatment of gonorrhea, usually causing disappearance of symptoms and reversal of bacteriologic findings within forty-eight hours. One course of treatment with a dosage of 160,000 units per case effected cures in 98 per cent, 80,000 to 120,000 units in 96 per cent and 50,000 units in 86 per cent. No significant differences in the final results were noted when a given total dose was administered in individual injections of either 10,000 or 20,000 units. Furthermore, little advantage was gained by prolonging the time of treatment schedules beyond twelve hours.

Factors such as duration of infection, previous fever therapy and race appeared to have no effect on the results of therapy.

Of the total of 126 failures to one course of penicillin, 85 were retreated, using a 100,000 unit dosage. Of these, 78, or 91.8 per cent, were cured. Thus, by retreatment of failures with a second course, 99 per cent cures were obtained. No case in the entire series proved to be penicillin resistant.

Complications of gonorrhea responded well to penicillin, although the more serious forms of complications required prolonged treatment with higher dosage.

Reactions to penicillin were inconsequential, and in no instance was it necessary to discontinue treatment for this reason.

Because of the known effects of penicillin on *Treponema pallidum*, the possibility of masking or delaying the development of early syphilis must be considered.

Finally, it should be recognized that the treatment of gonorrhea has been completely revolutionized in the past few years, first by the introduction of the sulfonamides and, more recently, by the development of penicillin. It is clear that the management of gonorrhea now belongs within the sphere of the chemotherapist, and that local treatment is rarely necessary and may do more harm than good.

ABSTRACT OF DISCUSSION

LIEUTENANT COLONEL IRVING S. WRIGHT, M. C., A. U. S.: This compilation of important data represents an encouraging example of cooperation in clinical research. This should encourage others to embark on similar studies when maximum data are needed in the shortest space of time. A few comments, based on experiences at the Army and Navy General Hospital and at many hospitals later visited may prove of interest. In some patients, both male and female, the cultures became negative within four to six hours after the initial dose. Certain of these patients had had profuse discharges, with positive cultures for six months or more. The possibility that the excretion of penicillin in the discharge is a factor in inhibiting the culture growth must be considered. Two patients, both men, had had profuse discharges for months. Smears from each were positive in the usual sense of interpretation; that is, many gram negative intracellular diplococci, which could not be differentiated from gonococci, were found. Cultures failed to grow the organism. One of these patients had twenty-seven negative cultures in a laboratory that grew practically 100 per cent positive cultures in the remainder of the gonorrhea patients. These 2 patients were treated with five and eight courses of sulfonamides respectively, with hyperthermia and with two courses of penicillin of 100,000 units each. This therapy had absolutely no effect on the discharge or on the organisms seen in the smears. The findings suggest that the organism may not be a true gonococcus, but that is as far as we are able to go. I should like to ask Colonel Turner whether he knows of other examples of this group. We have tried penicillin in the treatment of rheumatoid arthritis which arose during the acute phase of gonorrhea and continued after the discharge had ceased. The etiologic classification of these cases is difficult. They differ from the so-called acute gonorrheal arthritis reported in the paper under discussion. The treatment of patients with typical rheumatoid arthritis has been disappointing in our hands. The broader implications arising from the findings of this and similar studies cannot be overestimated. Once more the scientific approach is leading the way, but the problems of its application must be carefully considered. This is easy for members of the armed forces and relatively easy for the professional prostitute. Today, however, our great source of infection is from the amateur pick-up, the girl who comes from a surprising cross section of our population. The widespread use of penicillin in this group must be the result of careful but intense educational programs. A note of caution must be raised, however, against the widespread increase of promiscuity which may arise, with its resultant serious dislocations to our social structure.

DR. JOHN F. MAHONEY, U. S. P. H. S.: It would be an error not to call attention again to the point that the use of penicillin in the treatment of gonorrhea may have the effect of masking or greatly altering the symptoms of the invasion of a concomitantly acquired syphilis. As the product becomes more generally available and more generally used, an increasing number of instances of faulty and delayed recognition of the latter disease probably will be encountered. Repeated serologic tests for syphilis for at least two months following treatment appears to offer the best safeguard, and this feature may well become an important part of follow-up work. In much of the early work with penicillin, investigators have been faced with the necessity of working with limited amounts of the product. This has called forth efforts to refine the dosage to a point where the utmost in results would be produced by each unit available. In the future, and especially if the material becomes as plentiful as now appears certain, the concept that "the dangerous dose is the small dose" will probably gain adherents. The objective will then be to use a sufficient amount of the drug to produce a clinical response as rapidly as possible. In view of the non-toxic character of the substance, the utilization of larger amounts may be accomplished without an appreciable risk of producing untoward symptoms. The questions of total dosage, the duration of treatment, the interval between injections and the number of injections cannot be considered as established at the present even in the light of the favorable results which have been recorded in the present report. Products of greater purity and the development of preparations which are absorbed and excreted less rapidly may have the effect of permitting treat-

ment schedules to be utilized which are less burdensome and as effective as those in use at the present. The impact of the therapy on incidence of gonorrhea and especially on the public health approach to the disease forms an interesting field of speculation. Should the experiences of the future confirm the impressions which are inescapable on the basis of the material at hand, then surely control of the disease through the medium of the venereal disease clinic will require reorientation. A different type of facility may be needed to implement the new therapy. That gonorrhea may cease to be of major public health importance in the none too distant future seems to be an entirely reasonable assumption.

LIEUTENANT COLONEL THOMAS H. STERNBERG, M. C., A. U. S.: The existence or development of penicillin resistant cases of gonorrhea has been a possibility of great interest and of some concern to the Army. In the data presented by Colonel Turner it is of interest that no true instance of penicillin resistant gonorrhea was encountered, provided three courses of penicillin were administered. Since the termination of these studies, many thousands of individuals with gonorrhea have been treated with penicillin in various army hospitals, and particular efforts have been made to uncover cases not responding to adequate penicillin therapy. While such cases are not infrequently reported, investigation reveals that usually they have been labeled as penicillin resistant on the basis of either inadequate penicillin treatment or persistence of a mucoid discharge, which is bacteriologically negative and later proves to be nongonococcal in origin. I have just completed an extensive trip throughout the southwestern portion of the country, visiting numerous army hospitals routinely using penicillin in the treatment of gonorrhea. During these visits the relatively few instances of so-called penicillin resistant gonorrhea were investigated. In most instances the total dosage of penicillin did not exceed 200,000 units, and in no case was it possible to isolate a strain of gonococcus which was resistant *in vitro* to the more concentrated dilutions of penicillin. To date the army experience indicates that the incidence of truly penicillin resistant gonorrhea is at least unusual and further suggests that the term penicillin resistant gonorrhea should be applied cautiously and only after failure to respond to comparatively large doses of penicillin as determined by adequate clinical and laboratory studies.

DR. ALFRED COHN, New York: May I report the essential findings of a study on penicillin therapy in 100 women and 20 men who suffered from sulfonamide resistant gonococcal infections. This study is still in progress in collaborations with my associates Dr. Boris A. Kornblith and Dr. Isaak Grunstein. The 100 women were hospitalized for penicillin treatment at the gynecologic service of Dr. Howard C. Taylor Jr. at Bellevue Hospital. Our studies were directed first toward evaluating the optimal total dosage and second to determine an adequate time schedule for cure. The results of administering various amounts of penicillin in the female group point to the fact that a minimum total dosage of 100,000 Oxford units intramuscularly is both necessary and sufficient for bacteriologic cure. The time schedule that was found to be most satisfactory without failure averaged between six and nine hours. The penicillin was administered either in four intramuscular injections of 25,000 units each or by an initial injection of 50,000 units followed by two injections of 25,000 units each. Twenty ambulatory men who suffered for a number of months from sulfonamide resistant gonococcal infections with chronic complications, 18 with prostatitis and 2 with epididymitis, were treated at the Central Clinic of the Department of Health, City of New York. A total dosage of 100,000 Oxford units of penicillin was administered intramuscularly to all 20 patients. Two schedules of therapy were employed: 1. An initial injection of 50,000 units was followed by two subsequent injections of 25,000 units each at three hour intervals; total time of therapy, six hours. 2. An initial injection of 40,000 units was followed by two subsequent injections of 30,000 units each at two hour intervals; total time of therapy, four hours. Thus far no failure of therapy has been encountered in any of these 20 patients who have been followed up by repeated urethral and prostatic smears and cultures over a period of between two and four weeks. Urethral cultures taken at one hour intervals

after the initial injection of penicillin became negative between the third and fourth hour after treatment was initiated. Smears of urethral discharges showed involution and disintegration of the gonococci and leukocytes by the end of five hours in most cases. Our findings indicate that an adequate minimal dosage of 100,000 units of penicillin administered over a period of from four to six hours to ambulatory patients is a satisfactory routine in the treatment of sulfonamide resistant gonococcal infection.

COLONEL THOMAS B. TURNER, M. C., A. U. S.: In reply to Colonel Wright's question about observing the organisms which do not grow out on culture, we have observed a similar thing in our hospitals. We assume that it is due to the presence of penicillin and that they do not grow out.

PENICILLIN FOR THE TREATMENT OF CHEMORESISTANT GONORRHEA IN THE FEMALE

ROBERT B. GREENBLATT, M.D.

Surgeon (R) U. S. Public Health Service
AND

ANITA R. STREET

Laboratory Director, Southeastern Medical Center, Oakland Island
SAVANNAH, GA.

With the advent of the sulfonamides the eradication of gonorrhea from the human race seemed quite likely. The promise contained in the earlier reports for the treatment of gonorrhea with sulfonamides, however, has not been completely fulfilled. Moreover, the therapeutic results for the female have not been so good as for the male, because of vagaries in her anatomic makeup. The physiologic mucoid alkaline secretions of the cervix aid and abet the growth of the gonococcus; the anatomic arbor-like arrangement of the cervical glands conceal this micro-organism in protective depots for survival. Even against such odds the sulfonamides brought under control a very large number of women with acute and chronic gonorrhea. The exceptions were the females who harbored resistant strains or in whom, because of chronicity of long duration, the gonococcus had taken tenacious hold in the subepithelial layers of the mucosa lining Skene's ducts, Bartholin's glands, the endocervix or the fallopian tubes. Chronicity and chemoresistant strains proved a barrier that sulfonamides frequently failed to overcome.

The early reports of 85 per cent cures of gonorrhea with sulfonamides no longer hold, for the persistence of certain strains which have gradually permeated a selected stratum of the populace has reduced the effectiveness of sulfonamides to little better than 55 per cent. It is further true that improved bacteriologic technics have helped to uncover many carriers of gonococci in spite of complete absence of clinical signs and symptoms.¹ The sign on the door, namely a purulent urethral discharge, is not a worthy criterion on which to base a clinical diagnosis of gonorrheal infection. Too frequently, particularly in the old infected case, is it lacking. Too frequently, in spite of a frank urethral discharge, gonococci are not to be found and other organisms, among them the trichomonad, are common offenders.

Pelouze, the prophet of doom in the sulfonamide wilderness, was haunted by the specter of the carrier and the chemoresistant strain. He continually exhorted medical authorities to beware of the false security into which we have been lulled by sulfonamides. Shall we

1. Koch, R. A.; Mathis, E. N., and Geiger, J. C.: Ven. Dis. Inform. 25: 35, 1944.

be lulled into a similar state of complacency with penicillin? This much is known: that penicillin is an extremely effective bacteriostatic and bactericidal agent, many times more powerful and efficient than the sulfonamides. Much had been expected of other drugs in the past. Penicillin offers much now because it is effective against sulfonamide resistant strains. Will penicillin fast strains develop? Time is of the essence.

MATERIAL

This series comprises 551 females ranging in age from 3 to 48 years, studied at the Southeastern Medical Center during a given period. Of this number 54 per cent were of the Negro race and 46 per cent were white. It is revealing and surprising that 82 per cent of the white females had bacteriologically proved gonorrhea, while a similar diagnosis could be established in only 41 per cent of the Negro women (table 1). Although, comparatively, a far greater number of Negro than white women had clinical evidence of gonorrhea, such as urethritis, induration of the broad ligaments, scarring of the cul-de-sac or pelvic inflammatory masses, nevertheless, the diagnosis was confirmed bacteriologically twice as frequently in white females. Each patient had a minimum of six cultures in an effort to establish a diagnosis of gonorrhea.

One hundred and nine patients in this series were treated with penicillin, and of these 93 per cent had

TABLE 1.—Analysis of Patients Treated with Penicillin

Race	Females Studied for Venereal Diseases		Bacteriologically Proved Gonorrhea		Penicillin Treated	
	Number	Percentage	Number	Percentage	Number	Percentage
White.....	258	46.8	213	82.1	84	39.4

Total....	551	100	335	60.8	109	32.5

had one or more courses of sulfonamides. Several gonorrheic females received penicillin without a full course of sulfonamides because of sensitivity to them. Penicillin was administered on a few occasions without a prior course or completion of a course of sulfonamides because of certain considerations, such as pelvic peritonitis or acute exacerbation of a chronic salpingitis. Penicillin was dissolved in a few cubic centimeters of distilled water or saline solution and administered intramuscularly in 10,000 to 20,000 units at three hour intervals until 60,000 to 150,000 units had been administered. One 3 year old girl received a total of 25,000 units and two 9 year old girls each received 50,000 units. One patient had concomitant granuloma inguinale and received 1 million units (table 2). There were no untoward reactions resulting from penicillin therapy.

It is of interest that proportionately one and one-half times as many white females received penicillin as did Negro females. Following penicillin therapy four or more cultures were taken in 85 per cent of the cases. Cultures were taken daily for the first few days and then at intervals of one, two or more days. On the average 6 to 15 cultures were obtained in the greater number of instances (table 3). In 3 instances follow-up cultures were not obtained, as the patients were sent back for observation to the referring agency immediately after therapy and reports were not available at the time of writing. Five patients received a second course of penicillin because positive gonococcus cultures were obtained after a lapse of five or more days following

the administration of the first course. One of these, however, was not considered as a relapse but rather as a reinfection. The second round of penicillin varied from 120,000 to 300,000 units. These patients remained bacteriologically negative during the period of observation following the second course of therapy and were

‡ In all, 109 patients; 5 received a second course of penicillin therapy.

dismissed after 6 to 12 cultures as bacteriologically negative for gonorrhea.

The analysis of statistical data in this series reveals two important facts that require further study:

1. A laboratory diagnosis of gonorrhea was established in twice as many white as Negro patients, although the ratio of white to Negro in this series was practically 1:1.
2. Proportionately one and one-half times as many white patients as Negroes received penicillin therapy because of chemoresistance to sulfonamides.

Several questions arise:

1. Is a bacteriologic diagnosis more readily made in white gonorrheic women?
2. Are gonorrheic Negro females more responsive to sulfonamides?
3. Is there a racial factor?

Certain facts must be considered before drawing conclusions. White women are more apt to be seen during the acute phase of gonorrhea, and bacteriologic proof is probably easily obtained during this period. Then again, chronicity of long duration in the Negro group, as evidenced by chronic pelvic inflammatory disease, makes for greater difficulty in establishing laboratory proof of gonorrhea. Failure to obtain a positive gonococcus culture in such cases does not constitute a priori evidence of absence of gonorrhea. In 3 Negro females in whom gonorrhea was suspected, positive cultures were obtained only after the thirteenth, seventeenth and twenty-fourth culture respectively.

TABLE 3.—Cultures Following Courses of Penicillin

	None	1-3	4-5	6-10	11-15	16-20	21-25

Total.....	3	24	12	51	28	3	3

Are sulfonamides more specific for gonorrhea in the Negro race? It is the opinion in military circles that this is so, and this view is shared by Pelouze.² This phenomenon may be more apparent than real and is worthy of further study. If such a racial factor exists it may explain the proportionately larger number of white females for whom the administration of penicillin was required because of chemoresistance to sulfon-

2. Pelouze, P. S.: Ven. Dis. Inform. 25:76, 1944.

amides. We feel, however, that this discrepancy is not a real one. The study of the Negro female for a longer period of time, under more rigid tests, such as slight cauterization of the cervix, mild dilatation of the cervical os and repeated pelvic examinations, may yield a greater number of positive cultures in this group during the carrier and asymptomatic state.

ANALYSIS OF RESULTS WITH PENICILLIN THERAPY

Following penicillin therapy the cultures obtained within twelve to twenty-four hours usually were negative. In 9 instances positive cultures were obtained twenty-four hours after penicillin, in 3 after forty-eight hours, in 3 after seventy-two hours and in 4 after ninety-six hours. Patients in whom a positive smear or culture was obtained after the fifth day were considered to be therapeutic failures. In 4 patients positive cultures were obtained on the fourth and ninth days, fifth and seventh days, sixth and ninth days and the eighth day respectively. In 2 others positive smears but negative cultures were obtained, in 1 on the fourth and eighth days and in the other on the tenth day. In reality, 6 patients gave evidence that the gonococcus was not eradicated by the fifth day following penicillin. Positive cultures were obtained in 5 other patients who received penicillin therapy on being checked at various intervals by the referring agency after their dismissal from the hospital. Positive cultures were obtained on the tenth, seventeenth, twenty-first, twenty-fourth and sixtieth days respectively. In each instance it was believed that reinfection rather than a relapse occurred.

It must be said that, following penicillin, urethral discharge and symptoms of vaginitis, salpingitis and pelvic peritonitis frequently abate within twenty-four to forty-eight hours. On the other hand, purulent urethral and cervical secretions continued in many despite absence of bacteriologic proof of gonococcal infection.

CONCLUSIONS

Penicillin is an effective drug for the therapy of chemoresistant gonorrhea in the female. One hundred and nine patients received courses of penicillin; of these, 84 were white women and 25 were Negroes. Five hundred and fifty-one women (46 per cent white and 54 per cent Negroes) were studied for venereal diseases and in 61 per cent laboratory evidence to support the diagnosis of gonorrhea was obtained. Proportionately, one and one-half times as many white women received penicillin for chemoresistant gonorrhea. The impression that Negro women are more responsive to sulfonamides is more apparent than real. During the period of observation in this series, therapeutic failures were obtained in 5 women following penicillin. A favorable response was obtained after a second course of therapy.

The excellent results that are being obtained now with penicillin will not engender, it is hoped, too great a degree of optimism.³ The dosage of penicillin should

not be reduced to the minimum necessary for good results. It should be maintained at a sufficiently high level so that the development of penicillin resistant strains may be thwarted.⁴ To this end it is recommended that 150,000 units be used, although good results may be obtained with as little as 60,000 units. A warning note is sounded that asymptomatic carriers may develop and that penicillin resistant strains of gonococci may appear.

THE ROLE OF THE SKIN AND CORNEAL LAYER IN EDEMA FORMATION

G. E. BURCH, M.D.

AND

TRAVIS WINSOR, M.D.

NEW ORLEANS

With the present exacerbation of interest, because of the war, in the physiology of shock, of burns, of blood vessels and edema and of water and electrolyte balance it was considered advisable to review the role of the skin and especially the thin dead corneal layer of the epidermis in these states.

In the evaluation of the factors concerned with the regulation of edema formation, the role of the skin is neglected. The importance of the skin becomes apparent when the extravascular physical factors involved in edema are considered. The importance of tissue pressure in the regulation of edema formation is generally accepted today.¹ Tissue pressure becomes increasingly important as edema fluid accumulates,² ultimately becoming one of the most important factors inhibiting further progress of the edema. This is obviously true, for when the volume of intracellular and extracellular fluid accumulates the tissues become separated and the volume of the part increases. Because of the fibrous connective tissue, trabecules, blood vessels, nerves, lymphatics, tendons, muscle and other structures, the tissues tend to be held together and resist separation, thus resulting in an increase in the hydrostatic pressure of the tissues. As greater volumes of edema fluid gather, the absolute value of the tissue pressure increases, attaining extremely high values at times.³

It was also shown previously³ that the skin is an important factor which limits the accumulation of edema fluid. As edema fluid gathers in the tissues the part distends, the tissue pressure increases and the skin is stretched, exerting a counter force against the tissues and fluids within. This counter force contributes to the tissue pressure and thereby tends to limit edema formation. The resistance to distention or stretching offered by the skin reflected by the aforementioned counter force is most probably maintained to a larger extent by the fibrous connective tissue of the corneum, with the layers of the epidermis contributing a lesser but significant part. The role of the skin in the physical

limitation through the medium of tissue pressure is well known to every one who has seen the shiny smooth skin of the edematous leg and the wrinkled rough skin of the same leg after the edema has disappeared.

Once a part such as a leg has become fully distended and the skin has reached its limits of distention, the escape of fluid from the blood vessels cannot be any greater than the return of tissue fluid to the blood vessels unless the skin breaks and allows the escape of fluid to the outside. This phenomenon is well known clinically in patients with pronounced edema of the legs in whom the epidermis of the skin of the legs cracks and "weeps" edema fluid continuously until the edema state is relieved. It is usually only under such conditions that one is aware of the role of the epidermis in the limitation of quantity of water lost from the blood vessels. The epidermis of the skin, however, is continuously active as a factor inhibiting water loss from blood vessels in that it inhibits the loss of fluid from the tissues outside and in turn from the vascular system by preventing diffusion and oozing of water into the atmosphere. The importance of this influence is well known in burns and has been studied recently in living and dead skin.⁴ Although this role of the skin is active in the normal subject, its influence becomes even more significant quantitatively in the presence of edema, increasing in importance as the edema increases.

It was found⁵ that the corneal layer of the epidermis, a layer of microscopic thickness except in the palms and soles, was the layer of the skin that was of greatest importance in the inhibition of water loss by diffusion from the underlying tissues of the part. Niching the corneum of the skin of an edematous part permits the underlying edema fluid literally to flow at times as it escapes from the body. This is more vividly exemplified by the puncture of a blister cap, with the rapid escape of blister fluid. These simple experiments as well as others⁴ indicate the significant and peculiar role of the corneum in holding fluid within the body, thereby maintaining tissue pressure, inhibiting edema formation and the loss of vascular fluid.

In normal physiologic states⁶ little water diffuses through the epidermis of the skin. This is true even in the presence of much underlying edema fluid and the existence of pronounced distention of the corneum. This is again illustrated nicely by a blister.⁴

Were it not for the overlying very thin layer of corneum, fluid that escapes into the tissue spaces would diffuse through the skin to the outside and tissue pressure would not rise appreciably if at all. Fluid would also continuously escape from the blood vessels, upsetting water balance and electrolyte balance and resulting in pronounced disturbances in normal physiologic states. Further action of the corneal layer of the epidermis and the skin as a whole in local and general water and electrolyte balance is obvious from the previous discussion.

It is therefore well to remember that the "dead," keratinous, ever desquamating, thin corneum enjoys a

significant role in human physiology not only by protecting the body from trauma, bacterial invasion and the like but also in the maintenance of a normal water and electrolyte balance; the latter functions of the corneum are rarely if ever appreciated. There is a need for a better understanding of the physiology of the skin as well as a need for more careful and scientific care of the skin both in health and in disease and especially by quantitative and qualitative evaluation of its part in edema formation. Because as a general rule the corneum remains intact is no reason why it should be neglected in the consideration of problems of water balance.

Clinical Notes, Suggestions and New Instruments

ORBITAL CELLULITIS TREATED SUCCESSFULLY WITH PENICILLIN

H. O. SLOANE, M.D., PHILADELPHIA

Associate in Ophthalmology, Jefferson Medical College; Ophthalmologist to the Doctors Hospital

Orbital cellulitis is an inflammation of the retrobulbar tissue. It is an acute disease and usually begins with serious general symptoms, fever and pain. The lids are swollen; the conjunctiva is chemotic and the eyeball is usually displaced in the direction of the orbital axis and its mobility is impaired. This is due partly to mechanical protrusion and partly to simultaneous infiltration of the muscles and paresis of the nerves. Pain is dull in character and increased by movements of and pressure on the eyeball; but there are no points of tenderness, such as are encountered in periorbitis and sinusitis.

The course of the disease may vary; the condition may appear threatening, yet no suppuration takes place. In other cases pus perforates in a very short time through the lid or conjunctiva, producing a fistula which may heal quickly or last a long time.

ETIOLOGY

This condition may be caused by traumatism. A foreign body such as a sharp stick or the point of a pencil may be driven through the conjunctiva into the orbit and broken off, where it may be hidden and leave no visible wound or other trace.

Mumps, tonsillitis, puerperal fever and other infectious diseases may also cause the condition, as well as dacryocystitis, thrombophlebitis of the facial veins or a panophthalmitis. In 60 per cent of the cases (according to Foster) it originates from an inflammation of one of the accessory sinuses. The direction in which the eyeball is displaced is helpful in determining which sinus or sinuses are involved.

BACTERIA

The principal bacteria found are the staphylococcus and streptococcus, but the pneumococci and the typhoid and pyocyaneus bacilli may also be found.

COURSE OF THE DISEASE

This is a dangerous disease and may lead to blindness and even loss of life. Blindness may be caused by thrombotic embolism of the retinal vessels. Hemorrhages and optic atrophy may be observed. The condition may be produced by circulatory disturbances, compression of the optic nerve or toxic effects. Thrombophlebitis of the central vein plays an important part.

There may also be corneal complications, with perforating ulcers and phthisis bulbi.

Read before the Section of Ophthalmology, College of Physicians, April 20, 1944.
The medical department of the Jefferson Hospital assisted in the treatment of the patient.

OTHER COMPLICATIONS

Meningitis, abscess of the brain or thrombosis of the cavernous sinus may cause death and, according to Birch-Hirschfeld, does so in about 17 per cent of the cases.

REPORT OF CASE

History.—Charles C., aged 12, attended school on (Tuesday) Jan. 25, 1944. During the afternoon he complained of feeling ill and having a headache and some fever. He was visited by his family physician (Dr. Joseph A. Seiden), who could find nothing definitely wrong except that the child had an increase in temperature. On the following day, January 26, the lids of the left eye began to protrude and there was considerable proptosis of the eyeball accompanied by chemosis of the conjunctiva and pronounced edema of the lids.

I was called in consultation on Friday, January 28. On examination I found pronounced redness, swelling and edema of the lids of the left eye, with an extensive chemosis of the conjunctiva. The eyeball was proptosed about 15 mm. anterior to the right eye and was immobile. The pupil was dilated to 8 mm. but reacted to light. The tension of the eyeball was normal.

The ophthalmoscopic examination of the right eye revealed no pathologic change. The left eyeground showed a definite fullness of the optic disk, with considerable hyperemia. The veins were distended, broad and tortuous. The disk outlines were distinct. There were no hemorrhages or exudates present at this time.

edema of the conjunctiva and inflammation of both lids. The upper, middle and lower turbinates in both nostrils were boggy and obstructed drainage. The left nasal passage was filled with purulent exudate. Dr. Davis advised a good sized opening of the left antrum under the turbinate, with removal of the left middle turbinate and part of the left wall of the ethmoid. Dr. Davis felt it probable that pressure from the purulent

Fig. 2.—Appearance on March 29, after treatment with penicillin.

exudate had shoved the periosteum of the ethmoid away from the bone, thus pushing the orbital structure forward then laterally.

The patient was seen also by Dr. Wagers, who agreed with Dr. Davis and who arranged to operate on the following afternoon.

X-ray findings at this time, January 29, reported by Dr. Teplick, showed a large amount of fluid in the left antrum and the left ethmoid quite cloudy. There was no evidence of osteomyelitis or bone destruction. The right antrum and ethmoid were relatively clear. The frontal sinus was undeveloped.

Blood Studies.—When the patient was admitted, a white cell count was made and found to be 12,000. On January 31 another blood study was made, which disclosed hemoglobin 71 per cent, white blood cells 9,300, lymphocytes 21, monocytes 1. Blood culture showed no growth in forty-eight hours. A conjunctival swab taken on February 1 showed *Staphylococcus aureus* and *Bacillus xerosis*. A swab taken from the maxillary antrum showed 240 colonies of *Staphylococcus aureus*.

General Examination.—The boy was severely ill. Aside from the cervical adenopathy on the left side and the condition of his left eye, everything proved to be normal.

His past history revealed that he had mumps, measles, chickenpox and bronchopneumonia. The family history was negative.

Treatment.—When I first saw the patient, I immediately ordered sulfadiazine in fairly large doses. This was continued from January 28 until the 31st, when he was given penicillin. The sulfadiazine was discontinued, as he appeared to show no improvement from its use. During the first twenty-four hours 100,000 units of penicillin was administered intravenously; there-

Fig. 1.—Appearance of patient with cellulitis of the left eye on Feb. 1, 1944, the fifth day of disease.

I made a diagnosis of cellulitis of the left orbit and sent the patient to the Jefferson Hospital for further study and surgical treatment.

He was admitted to the hospital on January 29. His temperature was about 102 F. The pulse and respiration were rapid. He was examined by Dr. Warren B. Davis of the ear, nose and throat department the next morning, who found exophthalmos with lateral displacement of the left eyeball,

after, 50,000 units every twenty-four hours daily. This treatment was given from January 31 to February 9 inclusive. He received a total of about 500,000 units of penicillin.

Course of the Disease.—Following the first injection of penicillin the patient began showing improvement both locally and generally. The temperature showed improvement and continued to waver between 99.3 F. and normal. The pulse was correspondingly down from 110 to 80, varying, however, sometimes going up to 100 or more.

The local condition of the eye continued to show improvement. The edema and chemosis subsided gradually; the eyeball began to recede, and some motility was present on the third day after the penicillin was started. On February 12 the left eye was open. No photophobia or diplopia was present. Eye swelling, redness and chemosis were very much less. The temperature, pulse, respiration and blood pressure showed a normal range. The last culture of the left maxillary antrum showed no growth in the last forty-eight hours.

X-ray examination on February 10, as reported by Dr. Teplick, revealed complete clouding of the left antrum, also of the left ethmoids, although not as cloudy as on the previous examination.

The patient remained in the hospital until February 19. At this time the local condition of the eye was nearly normal. The eyeground showed much improvement. The optic disk was almost entirely clear and the color was normal. There was some tortuosity of the veins still present but not pronounced. The motility of the eye was good in all directions, and the patient could open and close his lids at will. Vision in both eyes was normal.

SUMMARY AND COMMENT

In a case of orbital cellulitis of the left eye in a boy of 12 the cause was established to be sinusitis involving the left ethmoids and the maxillary antrum. Operation was contemplated both for the sinus condition and locally to establish drainage and relieve the inflammation and swelling of the orbital tissues. However, under the continued use of penicillin intravenously for a period of ten days the condition cleared up completely, so that it was unnecessary to operate. Sulfadiazine in fairly large doses was tried without affecting the disease in any way and was discontinued when penicillin was administered. Local treatment was limited to applications of hot magnesium sulfate solution continuously and instillation of atropine sulfate 1 per cent three times daily.

1717 Pine Street.

BRONCHIAL ASTHMA AS A MANIFESTATION OF SULFONAMIDE SENSITIVITY

Theron G. Randolph, M.D., Chicago, and Frank F. A. Rawling, M.D., Ann Arbor, Mich.

As far as can be determined, convincing evidence of bronchial asthma as a manifestation of sulfonamide sensitivity has not been described, although it has been mentioned in this respect.¹

We report 2 cases, each with a history of asthma following the ingestion of a sulfonamide drug. In 1 instance the trial ingestion of sulfathiazole produced a severe paroxysm of asthma; in the second case the trial ingestion of sulfadiazine, although not producing clinical asthma, resulted in a definite diminution in the vital capacity.

CASE 1.—F. F., a man aged 44, a metal worker, was admitted to the University Hospital in status asthmaticus Sept. 21, 1943. The history as obtained from the patient and his local physician revealed that seven days prior to admission he had sought advice regarding a chronic nasal infection, presumably resulting from plucking nasal hairs. Large white tablets were prescribed

with instructions to take two every four hours, also ephedrine nose drops containing 2.5 per cent sulfathiazole.

Within twenty-four hours he developed a generalized rash, rhinorrhea, nasal stuffiness and conjunctival injection with periorbital edema. The unidentified tablets were then changed to sulfathiazole 0.65 Gm. every four hours, which was continued for a period of three days. The sulfathiazole nose drops were used in addition for a total period of seven days.

Chart 1.—Blood and vital capacity response following the trial ingestion of sulfathiazole (2 Gm.) in case 1.

His reactive symptoms were most pronounced the second day, thereafter subsiding to the point that he was feeling well by the fifth day and he returned to work on the sixth. At 10 p. m. of the seventh day of sulfathiazole therapy, September 20, he suddenly started to cough, followed by wheezing and dyspnea. These symptoms progressed alarmingly and were not relieved by epinephrine, ephedrine or morphine. He was admitted at 4:30 a. m. September 21.

There was no evidence of asthma or other allergic manifestations in his past or family history. There had been no previous treatment with sulfonamides as far as the patient or his physician was aware. Previous sulfonamide therapy cannot be excluded, however, as he had treated his nasal condition locally with numerous unidentified proprietary medications for the preceding six months.

On admission he exhibited extreme dyspnea and wheezing. Examination revealed the typical features of bronchial asthma, and there were no abnormal cardiac findings. The blood pressure was 130 mm. of mercury systolic and 100 diastolic. Laboratory data, including stereoscopic x-ray examination of the chest, were not outside normal limits.

He remained in status for three days in spite of rigorous treatment, including oxygen therapy, aminophylline intravenously and ether and oil by rectum. He did not become symptom free until a week after admission.

On his fifteenth hospital day, after he had been asymptomatic for a week, he voluntarily ingested 2 Gm. of sulfathiazole in a fasting condition. Within seven hours his vital capacity dropped from an initial level of 4,000 to 2,150 cc. At two hours he first complained of somnolence. At two and one-half hours he noted a sensation of heaviness in his chest. Four hours after ingestion he developed his initial coughing and dyspnea, sibilant rales were detected on chest examination for the first time and his vital capacity fell to 2,950 cc. Symptoms of asthma persisted for a total of twelve hours; cyanosis was present when the vital capacity was at the lowest level. With the exception of a reading of 2,350 cc. obtained on awakening the patient at 3 a. m., the vital capacity gradually returned to the preingestion normal within a period of forty-eight hours.

Total leukocyte and eosinophil counts were determined every half-hour for the first three hours, hourly during the next three hours and at less frequent intervals for a total of 127 hours. A diluent of phloxine and methylene blue dissolved in equal parts of propylene glycol and water, previously described by

Technical assistance was rendered by Miss Carol L. Stanton. From the Allergy Clinic, Department of Internal Medicine, University of Michigan Medical School. This study was financed in part by the Parke, Davis and Company.

1. Ratner, B.: Allergy, Anaphylaxis and Immunotherapy: Basic Principles and Practice, Baltimore, Williams & Wilkins Company, 1943. Leftwich, W. B.: An Intradermal Test for the Recognition of Hypersensitivity to the Sulfonamide Drugs, Bull. Johns Hopkins Hosp. 7:1: 26, 1944.

one of us,² was used in these determinations. With this method the eosinophils stain in the counting chamber; their enumeration in the same sample as used in determining the total leukocyte count gives more accurate values than obtained in the differential counts from stained films.³ The number of eosinophils per cubic centimeter of blood was obtained by counting the cells in nine squares of the counting chamber and multiplying by 22.2. Control counts were made from Wright stained films.

Variations in the blood findings and vital capacity are shown in chart 1. The preingestion total leukocyte count of 8,750 fell to 6,400 cells per cubic millimeter at one-half hour and then returned to the previous level. A count of 9,950 was obtained thirty minutes after the first food was taken at 4 p. m. Higher counts were obtained later, but a return to the preingestion normal did not occur until the third day.

The eosinophils showed a slight rise in the first hour (11.2 to 13.2 per cent); at the end of three hours they fell to 4.1 per cent, from which there was no significant change until ten and one-half hours. Successive counts thereafter showed a surprising rise to 29 per cent at thirty-five hours. A high level was maintained for the succeeding forty-four hours and was still elevated (14.0 per cent) at the conclusion of the period of observation. In chart 1 the eosinophil counts are plotted in absolute numbers.

The patient has remained free from asthma for the ensuing eight months period.

CASE 2.—M. M., a white woman aged 34, a secretary, gave a history of infantile eczema occurring during the winter months from the age of 5 to 7.

In May 1937 she moved to an old house and in August developed rhinorrhea, sneezing, itching of the nose and eyes and intermittent nasal obstruction. Asthma occurred for the first time in November and continued intermittently through the winter in spite of house dust hyposensitization and wheat avoidance. Trial ingestion of wheat precipitated increased rhinitis and asthma. In February 1939 she moved to a new house, and although the rhinitis continued it remained distinctly less troublesome and she had only two attacks of asthma after making this change.

In October 1941 she was hospitalized because of a complaint of chest pain accompanied by a temperature of 102.5 F. X-ray evidence suggested pneumonia. Pneumococci could not be

more pronounced and persisted for eleven days. On the fifth day a sore throat developed, followed on the seventh by nausea, backache and extreme fatigue, and the ninth day by a fine macular erythematous rash over the arms, back and buttocks. At this time cyanosis and dyspnea become more pronounced and she was placed in an oxygen tent. In spite of this measure the difficulty in breathing increased; the rash also became more prominent and generalized. Sulfadiazine was discontinued at this point. In the following twenty-four hours her breathing became easier and the cough more productive. Forty-eight hours after the drug had been stopped the headache and rash subsided. The fever, which had ranged between 100.0 and 101 F., returned to normal coincident with general improvement. However, extreme fatigue persisted for several days.

A total leukocyte count of 6,600 cells per cubic millimeter on admission prior to sulfadiazine therapy decreased to 4,800 on the fifth day but later returned to an average count of 7,000. The maximum count was 8,700 cells per cubic millimeter.

In December 1942 she had an upper respiratory infection associated with soreness of the throat of two weeks' duration. She received one dose of sulfadiazine (0.5 Gm.) at 1 p. m. At 4 o'clock she noticed flushing of the face and mild dyspnea, which progressed into severe asthma, her first attack in over three years. By 6 o'clock she had a fever of 101.0 F. and complained of fatigue, backache and generalized joint pains. Asthma persisted throughout the night. The following morning all symptoms had subsided except for residual fatigue and, incidentally, the soreness of the throat, which had not changed. Blood counts were not taken.

She had had no other sulfonamide therapy until she volunteered to take 0.5 Gm. of sulfadiazine at 9:30 a. m. Feb. 5, 1944. The drug was taken fasting, and similar studies were made as in the preceding case.

As may be noted in chart 2, a precipitous fall in the total leukocyte count occurred at one-half hour. From a preingestion level of 3,200 cc. the vital capacity fell to 2,300 two and one-half hours after ingestion, at which time she noticed flushing of the face. A frontal headache developed at three hours; this gradually became more severe and finally wore off at ten hours. Somnolence and fatigue followed. There were no residual symptoms the following day, although the vital capacity did not return to normal until forty-eight hours had elapsed. Aside from this measurement there was no other evidence of bronchial asthma. The temperature remained normal throughout the period of observation. As may be noted from chart 2, the initial neutropenia was followed by an increase to the preingestion level, from which the count gradually fell to between 6,000 and 7,000 per cubic millimeter. The eosinophil count decreased from a preingestion value of 3.7 per cent to 2.6 per cent at the height of symptoms at three and one-half hours, from which it increased to a maximum of 7.4 per cent twenty-five hours after taking the drug.

COMMENT AND SUMMARY

Two cases of bronchial asthma resulting from sulfonamide sensitivity were observed. In 1, status asthmaticus developed in a person with a negative past and family history of allergy on the seventh day of sulfathiazole nasal therapy. Two weeks after cessation of the drug and after the patient had been asthma free for a period of a week, a trial dose of sulfathiazole reproduced a typical asthmatic paroxysm, as measured by a drop in the vital capacity and confirmatory physical findings.

In a second case with a previous history of atopic dermatitis, allergic rhinitis and bronchial asthma, there was a recurrence of asthma after the first dose of the second attempt to prescribe sulfadiazine. Trial ingestion of the drug a year later resulted in a diminution of the vital capacity but no other evidence of asthma.

The eosinophils in both cases diminished during the stage of reactive symptoms but increased to relatively high levels twenty-four to forty-eight hours after ingestion.

700 North Michigan Avenue, Chicago—University Hospital, Ann Arbor, Mich.

Chart 2.—Blood and vital capacity response following the trial ingestion of sulfadiazine (0.5 Gm.) in case 2.

demonstrated as the causative organism, and a diagnosis of streptococcal pneumonia was made. She was treated with 6 and later 8 Gm. of sulfadiazine daily for a ten day period, receiving a total of 67 Gm. Twenty-four hours after the drug was started she complained of a dull headache, which gradually became

Council on Foods and Nutrition

The Council on Foods and Nutrition has authorized publication of the following report.

GEORGE K. ANDERSON, M.D., Secretary.

MARGARINE FORTIFIED WITH VITAMIN A

Margarine, sold under the legal designation "oleomargarine," is manufactured in forty-three plants primarily as a table fat or spread for bread, although it is also offered for baking and cooking. Present day margarine is the product developed through (1) improved methods of refining and processing fats, resulting from the additional knowledge of the chemistry of fats and oils, and (2) the application of nutritional research.

The first commercial production of margarine is recorded as by the Frenchman Mege-Mouries in Paris in 1870, who had earlier developed the product. The French government had assigned to him experimental work with fats as part of the effort to produce a cheaper product which would serve in place of butter in the domestic economy. The early product was made principally with oleo oil, but soon neutral lard and vegetable oils were used. With the development of hydrogenation first coconut oil and then other vegetable oils soon dominated the field. The accumulated knowledge and skill have made possible the utilization of the many domestic fats and oils which have been made available under present wartime conditions.

The legal definition and standard of identity of oleomargarine permits the use of animal or vegetable fat, oil or stearin or combinations of them to give not less than 80 per cent fat in the finished product. The fat ingredients are usually mixed with skim milk, although dried skim milk and water, milk or cream are permitted. Optional ingredients which are usually present and must be declared on the label are sodium benzoate (preservative), artificial flavoring, diacetyl or starter distillate, lecithin or monoglycerides and diglycerides, and salt. The use of artificial coloring has recently increased appreciably. The addition of vitamin A as fish liver oil or as a concentrate of vitamin A from fish liver oil is authorized, but this is still on an optional basis, although, when added, the finished product must contain not less than 9,000 U. S. P. units of vitamin A per pound.

The oils and fats used in the manufacture of margarine have varied widely over the years, and this may be expected in the future as availability and low prices are controlling factors. The factor of suitability is becoming a relatively less serious problem as technology overcomes the difficulties presented by the use of certain oils. This is currently being demonstrated by the improved keeping quality of margarine containing large amounts of soybean oil. The variation in the fat component of margarine as an indication of the industry's ability to adapt to changing conditions is illustrated by the consumption of foreign and domestic oils. In 1933 more than 75 per cent of the oil used in margarine was imported coconut oil. During that year the use of soybean oil was negligible, and only 9 per cent of cottonseed oil was used. In 1942 the use of coconut oil had dropped to 1 per cent, and none was used during 1943. In the latter year 90 per cent of the oil used in margarine consisted of cottonseed (50.4 per cent) and soybean (39.6 per cent) oils.

Margarine has long been a factor in the diet of a substantial group of persons, and with the wartime shortages of other spreads for bread it has increasing nutritional importance to a very large percentage of the population. The production of margarine has increased from the ten year (1930-1939) average of 312,675,325 pounds and 300,803,741 pounds in 1939 to 613,974,107 pounds in 1943, or 196.4 per cent of the production four years ago. Margarine contributed last year 3.2 pounds per capita of a total food fat disappearance of 45.8 pounds per capita and of total table fat consumption of 15.2 pounds per capita.

Thus, margarine represented 7.0 per cent of the total food fat and 21.1 per cent of the total table fat. The digestibility (rate or completeness of digestion) of the various food fats shows only small differences. In the case of the table fats factors of 96 to 97 found throughout scientific literature indicate equal digestibility.

The early deficiency of vitamin A in margarine has been corrected, primarily because of the application of the full force and influence of nutritionists throughout the country on the problem. The beginning of the widespread use of vitamin A in margarine dates from the authorization of its use in margarine manufactured in plants under Federal Meat Inspection in February 1941 and adoption of the Definition and Standard of Identity for Oleomargarine in June 1941. It is estimated that 85 per cent of the margarine was fortified by vitamin A during 1942. This increased to over 90 per cent in 1943, and industry reports indicate that now more than 99 per cent of the margarine sold to civilians contains not less than 9,000 U. S. P. units of vitamin A per pound. All of the nearly 90 million pounds purchased by federal agencies in 1943 was required to be so fortified. A small percentage of the total production classed by industry as "industrial sales" and sold to bakers and other establishments is unfortified. The Bureau of Human Nutrition and Home Economics recently estimated for 1943 an average of 7,000 international units of vitamin A per capita daily to have been available from food. Fats and oils, the bureau estimates, contributed approximately one tenth of this amount, but practically all of it was from table fat, as the vitamin A from other food fat is negligible. The compulsory addition of vitamin A is a needed safeguard equal in importance to the minimum fat requirement of the official standard.

The fact that margarine is cheaper to produce than butter is nutritionally important, and attempts to stigmatize it or restrict its distribution are undesirable. The Council is concerned wholly with nutritional value, and no consideration has been given to the economic effect of taxes reducing the margin of cost between the two products or their elimination. A continued demand that the two products be clearly identified may be expected, and this should be required; but the drastic, though effective, control of misrepresentation through fiscal measures of license and tax is still in controversy.

Many of the brands of margarine fortified with vitamin A have carried on the labels the seal of acceptance of the Council, indicating the accepted nutritional value of the product and the cooperation of the firms in adding vitamin A. In July 1943 the Council voted to restrict its scope primarily to those "special purpose" foods which have a definite relation to specific medical and health problems. Because of this action the seal will not be authorized on general purpose foods, including margarine, after the interval permitted to dispose of present stocks of containers. Advertising of these products which is concerned with nutritional education will continue to be considered and permitted to carry the seal on acceptance of the nutritional statements.

The Council takes this opportunity to reaffirm its confidence in the nutritional value of margarine containing vitamin A as follows:

1. Margarine contributes primarily fat to the diet.
2. The fat is equal in digestibility and caloric value to other food fats.
3. The standardized vitamin A content of fortified margarine was so set that it contributes this nutritional factor in amount equivalent to average butter in accordance with information available at that time. (Recent surveys indicate a higher average value for butter.)
4. The milk solids other than fat (1 per cent) present in both butter and margarine are of negligible nutritional importance.
5. When margarine is fortified with vitamin A the investigations that have been made lead to the conclusion that it can be substituted for butter in the ordinary diet without any nutritional disadvantage.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN E. SMITH, M.D., Secretary.

DICHLOROPHENARSINE HYDROCHLORIDE.—

DICHLOROPHENARSINE HYDROCHLORIDE
 Clorarsen.—“Dichlorophenarsine Hydrochloride, when dried in a vacuum desiccator over phosphorus pentoxide for twenty-four hours, contains not less than 25.3 per cent and not more than 27 per cent of total arsenic (As).”—U. S. P.

"Dichlorophenarsine Hydrochloride is usually distributed as a mixture with buffering agents and suitable substances to render its solution physiologically compatible with human blood. The label must indicate the names of the admixed substances, and the composition of the mixtures (containing Dichlorophenarsine Hydrochloride as the only active therapeutic agent) shall be approved by the National Institute of Health. Mixtures contain total arsenic equivalent to not less than 92.5 per cent and not more than 107.5 per cent of the labeled amount of Dichlorophenarsine Hydrochloride. Mixtures also meet the requirements for identification, loss on drying, thermostability, completeness of solubility and storage.

"Dichlorophenarsine Hydrochloride and its mixtures must be prepared in an establishment licensed for the purpose by the United States government upon the recommendation of the Surgeon General of the United States Public Health Service. Each lot of the product before being offered for sale must comply with the toxicity, labeling and other requirements of the National Institute of Health, and be released by the Institute."
—U. S. P.

For description and standards see the U. S. Pharmacopeia under *Dichlorophenarsinae Hydrochloridum*.

Actions and Uses.—In recent literature may be found reports of an arsenical antisyphilitic agent which apparently was discovered in the early part of this century but was cast aside as being too toxic for clinical use. Some years later there were published reports on its use in animals and in the treatment of yaws and human syphilis. It was not until 1941 that 3 amino-4-hydroxyphenyl dichloro-arsine hydrochloride was found satisfactory for the treatment of syphilis; apparently the earlier studies were based on the use of an unbuffered compound which would provide a very low pH .

The preparations now available on the market contain sufficient alkaline buffering agent to make neutral a prepared solution for injection. They contain approximately 26 per cent of trivalent arsenic. On the addition of sterile distilled water to an ampul containing the mixture of dry dichlorophenarsine hydrochloride and alkaline buffer a reaction takes place, with the result that arsenoxide is supposed to be formed. It has been claimed that the latter agent is the therapeutically active part of the compound.

(A preliminary report of the Council appeared in THE JOURNAL, Sept. 25, 1943, p. 208.)

Dosage.—Initial dose 0.03 Gm for women and 0.04 Gm. for men intravenously. The second dose may be increased to 0.04 Gm. for women and 0.06 Gm. for men. The maximum dose may be regarded as 0.06 Gm. Injections may be given every four to five days, as it is excreted rapidly.

For children, the initial dose should not exceed 0.5 mg per kilogram of body weight; the later doses should average between 0.5 mg. and 1.0 mg. per kilogram of body weight.

E. R. SQUIBB & SONS

Ampuls Clorarsen: 45 mg. and 67 mg. Each ampul contains the stated quantity of diechlorophenarsine hydrochloride admixed with three and one half times its weight of a mixture containing sodium citrate 96 parts and sodium carbonate 4 parts.

Ampuls Clorarsen: 0.45 Gm. and 0.67 Gm. multiple dose containers. Each ampul contains the stated quantity of dichlorophenarsine hydrochloride admixed with three and one half times its weight of a mixture containing sodium citrate 96 parts and sodium carbonate 4 parts.

PHEMEROL CHLORIDE.—[p-(2-methyl-4,4-dimethyl pentano-2) (phenoxy-ethoxy-ethyl)] dimethyl benzyl ammonium chloride monohydrate.— $C_{27}H_{42}O_2 \cdot NCl \cdot H_2O$ M.W.466.09. Phe-merol chloride has the following structural formula:

Actions and Uses.—Tincture Phmerol 1:500 and Solution Phmerol 1:1,000 (aqueous) are proposed as general purpose germicides and antiseptics.

Dosage.—Both the Tincture and the Solution are used full strength except in the nose and eye. For use in the nose and eye only the solution should be used, diluted with four parts of water.

Tests and Standards—

Phemerol chloride appears as colorless, odorless crystals possessing a very bitter taste. It may be recrystallized from a chloroform solution, by the addition of ether, in the form of thin plates, which may assume a hexagonal shape. These crystals possess a high birefringence, parallel extinction and positive elongation and are biaxial with refractive indexes of 1.580 and 1.560. These crystals and the original material sinter slightly on the hot stage at 120 C. and melt at 164-166 C. The η_{sp} of a 1 per cent solution of phemerol chloride is between 4.8 and 5.5.

Mineral acids and many salt solutions precipitate phemerol chloride from solution, more concentrated than 2 per cent, as an oil which crystallizes on drying and has the same properties as phemerol chloride. A solution of phemerol chloride yields a flocculent white precipitate with soap solutions. To 1 cc of a 1 per cent solution of phemerol chloride add 2 cc of ethanol, 0.5 cc. of dilute nitric acid and 1 cc of silver nitrate solution; a flocculent white precipitate appears, which is insoluble in dilute nitric acid but soluble in dilute ammonia water.

Dissolve 0.1 Gm of phenmerol chloride in 1 cc of sulfuric acid, add 0.1 Gm of sodium nitrate and heat on the steam bath for three minutes. Dilute the solution to 10 cc, add 0.5 Gm of granulated zinc and warm for ten minutes. Cool, add 0.2 Gm of sodium nitrite to 1 cc. of the clear liquid and add this mixture to 0.03 Gm of G salt (sodium 2 naphthol 6,8 disulfonate) in 1 cc of ammonium hydroxide. the solution turns orange and a brown precipitate may appear.

Transfer approximately 1 Gm of phemcerol chloride, accurately weighed, to a tared platinum dish and dry in an oven at 100 C. to constant weight the loss in weight is not less than 3.5 nor more than 4.2 per cent. Ignite the residue. the weight of ash is not more than 0.1 per cent.

Transfer approximately 2 Gm of phemerol chloride, accurately weighed, to a 100 cc. flask, dissolve in 30 cc of water; add 10 cc of nitric acid and 50 cc of tenth normal silver nitrate, dilute to the mark, mix well and filter through a dry paper. To 25 cc of the filtrate add 1 cc of 10 per cent ferric ammonium sulfate and titrate with tenth normal ammonium thiocyanate the chloride content is not less than 7.6 nor more than 8.0 per cent, calculated to the dried substance.

Transfer an accurately weighed sample of phemeral chloride to a kjeldahl flask and digest with sulfuric acid in the presence of selenium, cool, dilute with water, make alkaline with sodium hydroxide, distill the ammonia into the standard acid solution and titrate the excess acid: the nitrogen content is not less than 2.6 nor more than 3.1 per cent.

Dissolve approximately 100 cc. of 10 per cent normal sodium thiosulfate, accurately weighed, in water to make 100 cc. of solution. Transfer exactly 5 cc. of this solution to a 100 cc. flask, add 5 cc. of buffer solution and 250 Gm. of sodium acetate and 250 cc. of 36 per cent acetic acid, mixed with water to make 1 liter) and 50 cc. of 0.00667 molar potassium ferricyanide (prepared by dissolving 2.1948 Gm. of potassium ferricyanide in water to make 1 liter and standardized against 0.01 normal sodium thiosulfate). After mixing well, allow the mixture to stand for one hour and filter through dry No. 1 Whatman paper. Discard the first 20 cc. and to the next 50 cc., accurately measured, add 5 cc. of 10 per cent potassium iodide solution and 5 cc. of diluted hydrochloric acid. After one minute add 10 cc. of 10 per cent zinc sulfate solution and titrate with 0.01 normal sodium thiosulfate, using starch as an indicator; the percentage of phemeral chloride calculated as the monohydrate is not less than 97 per cent nor more than 103 per cent of the original substance. The percentage of phemeral chloride monohydrate = $[(cc. \text{ of } 0.00667 \text{ M } K_3Fe(CN)_6 - 3/2 \times cc. \text{ of } 0.01 \text{ N } Na_2S_2O_3) \div 9.326 \times 40/wt. \text{ of sample}]$.

The reactions involved are as follows:

$$\text{K}_3\text{Fe}(\text{CN})_6 + 3 \text{C}_2\text{H}_5\text{O}_2\text{N Cl}$$
$$\rightarrow (\text{C}_2\text{H}_4\text{O}_2\text{N})_3 \text{Fe}(\text{CN})_6 + 3 \text{KCl}$$
$$2 \text{K}_2\text{Fe}(\text{CN})_6 + 2\text{KI} \rightarrow \text{I}_2 + 2\text{K}_4\text{Fe}(\text{CN})_6$$

PARKE, DAVIS & COMPANY

SATURDAY, SEPTEMBER 16, 1944

THE HISTORY OF PENICILLIN

Recently the *British Medical Journal* said editorially¹ that the history of penicillin is essentially the story of three distinct developments: "The first was Fleming's discovery;² the second was the victory of Florey and his colleagues, who showed how to obtain penicillin in a relatively pure form and who demonstrated its clinical use";³ the third "victory," the editor generously points out, lies in the American success in large scale production of the drug. Sir Howard Florey⁴ in the same issue of the *British Medical Journal* gives a detailed survey of the development of penicillin studies. He mentions that in 1877, prior to Fleming's disclosure, Pasteur and Joubert⁵ had observed that cultures of anthrax ceased to grow when contaminated with air bacteria; this, Florey believes, was the first evidence that a substance produced by one organism is capable of arresting the growth of another. In the years that followed, many other "antibiotics" were discovered; one, an extract from *Bacillus pyocyaneus*, was placed on sale in Germany in 1930 as an unguent for local application to the skin lesions arising from anthrax.⁶

After noting conspicuous inhibition of growth in a colony of *staphylococcus* contaminated by mold, Fleming subcultured the mold in broth and found that a strong antibiotic, nontoxic to animals, passed into the broth from the mold;² the mold was later identified by Thom in this country as *Penicillium notatum*, and Fleming designated the antibiotic agent "penicillin." He found that penicillin inhibited the test tube growth of many gram positive bacteria known to be highly pathogenic to man; he also noticed that his penicillin-containing broth did not disturb white blood cells; on applying the solution to several clinical cases of local skin infection he reported⁴ that the results "appeared to be superior to dressings containing potent chemicals."

Several years later Clutterbuck, Lovell and Raistrick, stimulated by Fleming's study, attempted to extract penicillin, but their efforts were largely unsuccessful; they concluded that the penicillin was too "labile" to be of clinical use. In this conclusion Sir Alexander Fleming reluctantly concurred. If one may judge by his published work, Fleming then abandoned further study of the agent until 1941,⁸ except as he used it for differential culture.⁹

The successful isolation of penicillin, the clearest proof of its clinical usefulness, its assay and dosage, as well as the mode of its excretion from the body are credited to Howard Florey and his resourceful associates at Oxford. In 1929, the year of Fleming's first paper, Florey began work on lysozyme,¹⁰ an antibiotic discovered by Fleming in 1922 and ultimately crystallized by Roberts in 1937.¹¹ During the next ten years Florey continued his study of various antibiotics, firm in the conviction that one nontoxic to human beings would be found which would be of value in treating human infections. The discovery of the clinical effectiveness of penicillin was thus an outcome of a broadly conceived program of study and not an advance immediately associated with the war. Ultimately the war immeasurably expedited the development of penicillin, but during the early stages of the work wartime restrictions considerably impeded the study; for, once it had been disclosed how penicillin might be successfully extracted, it proved impossible in England (in 1940) to initiate large scale production.

Florey first directed his attention to penicillin in 1938, when he was joined by an able continental biochemist, Dr. E. Chain; between them a plan was laid for a systematic study of penicillin and other naturally occurring antibacterial agents. Drs. Florey and Chain were presently joined by Drs. E. P. Abraham, A. D. Gardner, Norman G. Heatley, M. A. Jennings, J. Orr-Ewing, A. G. Sanders, C. M. Fletcher and also by Lady Florey, a physician of competence who has been largely responsible for studying the effectiveness of penicillin applied to locally infected areas. The ultimate success of the research largely depended on the development of a reliable procedure for assay. The test adopted was worked out by the microchemist of the team, Dr. Norman Heatley, and consisted in determination of the rate of inhibition of growth of a standard bacterial culture. Through the use of an ingenious extraction method involving the passing of impure acid penicillin broth from a watery solution into an organic solvent (ether or amyl acetate) and the subsequent passing of the purified agent again into water (shaken with alkali), they obtained sufficient penicillin for clinical trial. first patient was treated on Feb. 12, 1941; the response was dramatic, but the supply of penicillin ran out and shortly thereafter the patient had a relapse and died. As might have been expected, the Oxford team encountered difficulty in obtaining suitable cases for clinical trial, and patients eventually turned over to them were generally moribund with advanced septicemia. By June 1941 6 such patients had been treated intravenously; all had responded, but 2 had died when the penicillin supply became exhausted.¹²

Undeterred by difficulties and an apathy that would have caused many to abandon the work until after the war, Florey, accompanied by Dr. Heatley, came to this country in July 1941 under the auspices of the Rockefeller Foundation, requesting that the National Research Council in Washington lend a hand in the medical study of penicillin, and more particularly in the attack on the problem of production. Through the foresight of Ross G. Harrison, chairman of the National Research Council, Florey was put in touch at once with the fungus laboratories of the Department of Agriculture, and through the cooperation of Dr. Coghill, director of the Fermentation Division of the Department of Agriculture's research laboratory at Peoria, new methods were worked out for increasing yield; within a few months large scale production of penicillin was begun by a group of enterprising American drug houses. The earliest patient to be studied in this country under the auspices of the Office of Scientific Research and Development was first treated with penicillin on March 14, 1942 in New Haven, Conn., an advanced case of hemolytic streptococcus septicemia, which responded most dramatically to the drug.¹³

Dr. Florey had returned to England in September 1941. Dr. Heatley remained in this country for some twelve months to assist in the negotiations for the large scale production of the drug; during this time Heatley rendered invaluable assistance in supervising assay of the early yields. Professor Florey devoted the following year (1942) to studying ways of purifying penicillin and, in association with Lady Florey, conducted a highly significant investigation on local application of penicillin; since supplies were still low there was too little available for general administration.¹⁴ In the summer of 1943 Florey and Brigadier Hugh Cairns, consulting neurosurgeon to the Royal Army Medical Corps, were sent to North Africa by the British War Office to study the uses of penicillin in war wounds. They returned three months later with a radical report which insisted¹⁵ that open flesh wounds and wounds of the head can be safely and tightly closed if dealt with early, provided penicillin solution is admin-

istered locally in the wound after thorough débridement. Their initial experience has been strongly vindicated during the past year by other British medical officers as well as by medical officers of our own Army and Navy. To quote a conservative report,¹⁶ "The percentage of scalp and brain wounds that heal by primary union has always been a high one when operation is performed at special neurosurgical units. In Italy, with greater infectivity of the terrain, this standard tended to deteriorate whenever penicillin was in short supply but was maintained when penicillin-sulfathiazole powder was insufflated to surface wounds and into depths of brain." Less conservative, but not less significant, is Florey and Cairns' original statement¹⁵ that of 171 recent (three to twelve days) soft tissue wounds 104 closed by primary union, 60 closed with some degree of granulation and 7 were classified as failures. "None of the patients," they add, "in this series has been placed in danger [i. e. there were no fatalities]. This is a remarkable fact when we consider that the wounds closed included large and purulent wounds of the worst type—for example, large buttock wounds infected with hemolytic streptococci and clostridia. Only once was it necessary to release the stitches; this was in a penetrating chest wound and cellulitis of the chest wall. . . . Cases with complete union (104) call for no comment. In cases with subtotal union (60) the gaping area usually healed rapidly by granulation. The failures (7) occurred in the early stages of the investigation and could usually be attributed to errors in technique of skin closure and rarely to persistence of pyogenic cocci. These patients came to no harm, and the attempt at closure did not interfere with their healing by granulation." A wound which heals by primary intention requires three weeks; if granulation occurs, six to twelve weeks may elapse. The military significance of this is too obvious to require comment. Indeed, many have come to feel that penicillin will transform our entire concept of management of wartime injuries, and it will no doubt have a similarly far reaching effect on civilian traumatic surgery.

Sir Howard Florey had scarcely returned from North Africa when he was summoned early in 1944 to Moscow, where he was able to give our Soviet allies first hand information concerning penicillin, particularly with regard to local administration in war wounds; on his return from the Soviet Union, Australia, the country of his birth, requested his counsel.

The *British Medical Journal* gives deserved and generous credit to Dr. A. N. Richards, chairman of the Committee on Medical Research, and to the Office of Scientific Research and Development for sponsoring the medical aspects of the penicillin program in this country. One can only add that part of Dr. Richards' wise direction of the program lay in his fortunate selection of the Division of Medical Sciences of the National Research Council working through the Committee on

Chemotherapeutic and Other Agents with its succession of able chairmen (Col. Perrin Long until July 1942 and thereafter Dr. Chester S. Keefer) as the official body responsible for supervising and directing both the formidable production schedule and the various research projects, two of the most significant of which were reported upon in last week's number of *THE JOURNAL*. The story of penicillin will long exemplify the highest traditions of medical research and, incidentally, the rich fruits of a sound international cooperation in wartime.

THIOUREA AND THIOURACIL IN TREATMENT OF THYROTOXICOSIS

After a study of the life cycle of persons with thyrotoxicosis, Fitz¹ concluded that the operative treatment of toxic goiter is generally successful but that the ultimate result is uncertain. The removal of the thyroid interrupts a vicious circle but does not reach the fundamental cause of the disorder; thus it is not a curative procedure. Two complications following operation are so frequently encountered as to be a definite hazard—the development of hypothyroidism or of recurrences.

The recent discoveries reported by the MacKenzies and McCollum² and Astwood³ point to the inhibition of function in an endocrine gland by the administration of certain chemical compounds. The MacKenzies, while investigating the possibility that sulfaguanidine, when fed to rats on a purified diet containing synthetic B vitamins, might prevent the synthesis of additional essential nutrients by the intestinal flora, observed that animals which received the drug for periods varying from six weeks to sixteen weeks showed without exception hypertrophy and hyperemia of their thyroid glands. The glands were from three to eight times larger than those of control animals which received the same diet without sulfaguanidine. The thyroid hypertrophy was accompanied by a definite fall in the basal metabolic rate. Both these changes were prevented or cured by administration of thyroxin but not by increasing the iodine content of the diet. At about the same time Richter and Clisby observed enlargement of the thyroid associated with loss of weight and other toxic reactions in rats fed phenyl thiourea in their drinking water. Accompanying this increase in weight of the thyroid, microscopic changes characterized by the continued heightening of the acinar epithelium and its encroachment on the concomitantly diminishing and vacuolated colloid were observed. The basal metabolic rate in adult rats which received sulfaguanidine for five to seven days dropped 10 per cent;

by the tenth to the fourteenth day it was —20 per cent, a level which was maintained to the end of the experiment at forty days. Addition of vitamin C and para-aminobenzoic acid enhanced the thyroid effect of sulfaguanidine. The addition of sodium iodide did not interfere with the thyroid effect of sulfaguanidine. In contrast with the foregoing results desiccated thyroid and thyroxin, when added to the diet, entirely prevented the thyroid enlargement and the microscopic changes. Kennedy found that oral administration of allyl thiourea to rats produced not only thyroid hyperplasia but an alteration of the cellular pattern of the anterior pituitary as well. Gersh and his associates established that the presence of the hypophysis is essential for the production of thyroid hyperplasia and hypertrophy by sulfaguanidine. They concluded that the sulfonamides and thioureas probably exert a depressing influence primarily on the functional activity of the thyroid and hence on the basal metabolic rate, and that thyroid hyperplasia is a reflection of increased pituitary activity resulting from the depression of thyroid function.

Astwood³ repeated these experiments and found that the hypertrophied glands rapidly regressed toward a normal condition on the cessation of treatment. Vascularity quickly decreased, the epithelium became flattened, colloid accumulated, and the size of individual follicles and the total size of the glands decreased. These retrogressive changes occurred fully as rapidly as the hyperplasia. Astwood likewise found that hypophysectomized rats did not develop thyroid hyperplasia on a 2 per cent sulfaguanidine diet. In spite of the histologic picture of overactivity, these animals did not present signs of hyperthyroidism; in fact, after a variable period of time the animals whose thyroids were hyperplastic began to exhibit distinct signs of hypothyroidism; that is, subnormal growth and development, lessened food intake and lowered basal oxygen consumption. The coexistence of thyroid hyperplasia and a lowered rate of metabolism suggested that the drug either exerted an action which inhibited the normal effect of the thyroid hormone on tissues in general or else that it interfered in some way with the adequate production of normal thyroid hormone. In either case the goiter would be the result of a compensatory hyperplasia which could not completely make up for the induced deficit. The mechanism of the goitrogenic action of these substances apparently resides in an interference with the synthesis of the thyroid hormone. The mode of action of these drugs, according to Astwood, appears to be an interference with the enzymatic synthesis of thyroid hormone. The exact site of block is still not known, but it is definitely established that the thyroid is rendered incapable of utilizing iodine for these processes. The resultant thyroid insufficiency leads via anterior pituitary stimulation to an ineffectual hyperplasia of the thyroid acinar cells. C.

G., and MacKenzie, Julia B: Effect of Sulfonamide- and Thioureas on the Thyroid Gland and Basal Metabolism, *Endocrinology* 32: 185 (Feb.) 1943.

3. Astwood, E. B.; Sullivan, J., Insell, Adele, and Tislowitz, R.: Action of Certain Sulfonamides and of Thioureas on the Function of the Thyroid Gland of the Rat, *Endocrinology* 32: 210 (Feb.) 1943.

more than a hundred compounds investigated by Astwood⁴ 2-thiourea was found to be the most highly active. The minimal lethal dose of this substance for rats was more than a hundred times the dose necessary to produce a detectable thyroid effect. Thiourea and thiouracil appear to be the most promising. There appears to be a variable latent period following the initiation of treatment before the metabolic rate begins to fall and a similar though somewhat shorter period before clinical improvement is subjectively and objectively apparent.

Astwood⁵ administered to 3 patients with thyrotoxicosis thiourea in doses of 1 to 2 Gm. per day or of thiouracil in doses of 0.2 to 1 Gm. with a resulting relief of symptoms and a return to normal of serum cholesterol and the basal metabolic rate. A latent period of one to two weeks occurred before a sustained improvement during treatment and a return of hyperthyroidism when therapy was discontinued. One of the patients developed agranulocytosis on the thirty-seventh day of therapy but recovered in seven days on withdrawal of the drug. Himsworth⁶ administered thiourea or thiouracil to 6 patients with thyrotoxicosis, and the results were as striking as those of Astwood. He did not observe any toxic effects of the drug. Williams and Bissell⁷ found that thiouracil is rapidly absorbed and is rapidly excreted. They treated 9 thyrotoxic patients with thiouracil and noted clinical improvement, which continued until all the symptoms disappeared within four to seven weeks. The basal metabolic rate fell progressively downward. The enlargement of the thyroid associated with thiouracil treatment which occurred in 3 of their patients and the increase in the pathologic state of the eyes in 1 patient suggest that in human beings, as in animals, thiouracil leads to excess thyrotropic hormone activity. Rawson and his collaborators⁸ administered thiouracil to 19 patients with toxic diffuse goiter. They report lowering of the basal metabolic rate, relief of symptoms, increase of hyperplasia of the thyroid with loss of colloid and increase in vascularity and in some instances increased lymphoid hyperplasia. They have also noted a decreased avidity for iodine by the thyroid gland, as shown by greatly impaired correlation of radioactive (tracer) inorganic iodine, with increased elimination in the urine. Impairment in the physiologic activity in the thyroids of persons treated with the drug was seen when tested on patients with myxedema. In patients previously treated with iodine the thyroid effects were delayed. They

conclude that these facts are consistent with the theory that thiouracil acts by preventing or blocking the utilization of iodine in the synthesis of thyroid hormone within the thyroid gland. Apparently, under the influence of thiouracil new active thyroid hormone is produced. Cessation of active thyroid hormone production is believed to stimulate the thyrotropic activity of the pituitary, and this in turn causes further hyperplasia of the thyroid, which however does not overcome the thiouracil block to active thyroid hormone production. Paschkis and his collaborators⁹ treated 21 cases of thyrotoxicosis with thiourea or thiouracil. Improvement was usually noticed after four to six days of treatment, with complete suppression of thyrotoxic manifestations after two to three weeks. One gram of thiouracil was effective in most cases. The drug proved particularly valuable in cases in which operation was deemed inadvisable. An attempt was made to establish a permanent dosage level rather than to employ intermittent treatment. After full effect was achieved, doses as small as 0.1 to 0.2 Gm. proved satisfactory. Myxedema developed in 2 cases and subsided after the drug was temporarily discontinued. Toxic manifestations from thiouracil consisting of skin eruptions, fever, arthralgia, leukopenia and jaundice were observed in 3 cases.

Gabrilovè and Kert¹⁰ treated 9 patients, 3 of whom developed toxic effects. One patient developed fever, general lymphadenopathy and skin eruption. Another patient presented fever and skin eruption, while the third patient showed moderate leukopenia. St. Johnston¹¹ administered thiourea for thyrotoxicosis to 3 patients and reports that all 3 developed toxic symptoms which were strikingly similar. The symptoms consisted of pyrexia from 101 to 104 F., occurring eight to ten days after administration of the drug, mild leukopenia with monocytosis, and a maculopapular eruption.

Elsewhere in this issue (page 153) Reveno reports 9 cases of toxic adenoma treated with thiouracil. Six showed a satisfactory response, while 3 were failures. One of the latter patients had diabetes and had been taking iodine for six years. The second responded favorably at first but developed a hemorrhage into the gland and thyroidectomy was done. The third was a patient who, while showing some clinical improvement, failed to show a drop in basal metabolic rate during the short period under observation.

Whether or not thiouracil will prove to be a satisfactory substitute for surgical treatment of toxic goiter cannot be stated on the basis of present limited experience. The drug promises to be of great value in cases in which operation is inadvisable or contraindicated.

Current Comment

NEUROFIBROMATOSIS AND OSTEITIS FIBROSA CYSTICA

An extensive study and reevaluation of the apparent relations of neurofibromatosis (von Recklinghausen) and osteitis fibrosa cystica has been presented recently by Thannhauser.¹ On the basis of reports of simultaneous occurrence of nodular cutaneous neurofibroma, pigmented areas of the skin and osteitis fibrosa cystica in a single patient, a coherence of neurofibromatosis and osteitis fibrosa cystica is suggested, since the occurrence of these symptoms of two rare diseases in one person is not likely to be mere coincidence, Thannhauser says. Fibrocystic involvement of localized areas of the skeleton, especially the long bones, occurs in neurofibromatosis together with café au lait spots and cutaneous neurofibromas. Although microscopic examination of the osseous fibroma does not reveal nerve structures within the fibroma, whorls of spindle cells are occasionally found and may be considered to reflect its neurofibromatous origin. Thannhauser believes that hyperpigmented areas are the expression of underlying neurofibromatosis even without the appearance of neurofibromatous nodules. The presence of similar endocrine symptoms, especially the concurrence of precocious puberty and pigmented blotches of the skin in neurofibromatosis and also in osteitis fibrosa cystica disseminata offers additional corroboration of the belief that the two disturbances are related. The implication is strong that the anatomic structures which underlie the endocrine symptoms in cases of simple neurofibromatosis are the same as those of osteitis fibrosa cystica disseminata.

SYNTHESES IN THE INTESTINE

The first demonstrations of vitamin K deficiencies were made with chicks as experimental animals. In this species the failure to produce prothrombin through lack of vitamin K can be brought about by dietary adjustment alone. Later similar experiments were carried out with canaries, pigeons and ducks. Ordinary laboratory mammals—dogs, mice, rats—do not readily show a reduction in prothrombin level in the blood when restricted to experimental rations lacking vitamin K. However, if sulfanilylguanidine and succinylsulfathiazole are added to these diets, hemorrhages can be produced in rats.² In a recent study Daft and his co-workers² have extended the list of sulfonamides used and have shown that when the hemorrhages occur there appears also a severe hypoprothrombinemia. At a level of 1 per cent in the diet sulfapyrazine, sulfadiazine and sulfathiazole were much more effective in this respect than were sulfaguanidine, sulfanilamide and succinylsulfathiazole. The fact that the order of effectiveness of the sulfonamide drugs in producing the vitamin K deficiency is much like that observed in their bacterio-

static action on *Escherichia coli*, together with the observation that this group of organisms is particularly active in the synthesis of vitamin K, emphasizes anew the point of view that various types of intestinal bacteria exert a beneficent influence. The synthesis of vitamin of the B complex group, early reported in experimental animals, was recently³ cited again as a contributing factor in human nutrition, and attention has been called to the possibility of amino acid production by these organisms.⁴ Further investigation will doubtless reveal other ways in which this symbiotic activity in the intestine is of value to the host.

DIET AS PREDISPOSING FACTOR IN RHEUMATIC FEVER

In a recent report by Peete¹ observations are summarized on patients seen in clinic and private practice over a four year period who showed any signs of *rheumatic fever or rheumatic heart disease*. The patients were given a list of foods with instructions to check after each meal all the foods eaten and to write in any additional ones taken which did not appear on the list. The survey included a comparison of the dietetic habits of 50 patients, some with acute and some in the chronic state of rheumatic fever, as compared with 25 normal school children. A comparative study showed that the average diet of the rheumatic patient was low in those foods which supply vitamins A and D and minerals, especially calcium, phosphorus and iron. Some deficiency in proteins and an excessive intake in starchy foods and refined sugars also was apparent. The diets of both groups showed a restricted use of eggs. It was significant, Peete believed, that the average number in families of 75 rheumatic patients was 7.5 members per family, whereas the average in the control group of better economic status was 4.5. Among the conclusions of this study were that the incidence of acute rheumatic fever and rheumatic heart disease increases as exposure to the sun decreases; few recurrences of active infection developed when families cooperated satisfactorily in the correction of the deficient diet and in addition of cod liver oil to these diets; poor dietary habits were found among those even with adequate financial means. Finally, this investigator felt that the deficiency leading to the development of rheumatic infection closely follows the incidence of clinical rickets and that it alters immunity to the infective organism that produces the clinical picture of acute rheumatic fever. He emphasizes the importance of adequate amounts of vitamins A and D, milk, protein and sun bathing in the prophylaxis and prevention of recurrences of this disease. The conclusions expressed should be accepted with reserve. The genesis of rheumatic fever has not yet been explained: most features of the disease would appear to label it as due to a specific agent not yet identified, although numerous precipitating or predisposing factors presumably occur, among which diet may be included.

MEDICINE AND THE WAR

ARMY

REORGANIZE AIR SURGEON'S OFFICE

The War Department recently announced the partial reorganization of the Air Surgeon's office and reassignment of key officers of the Medical Service, Army Air Force. Brig. Gen. Charles R. Glenn, surgeon of the Army Air Force Training Command, was assigned deputy air surgeon on the staff of Major Gen. David N. W. Grant, the Air Surgeon, effective August 15. He succeeded Col. Walter S. Jensen, who has been assigned to an important post overseas. Other new assignments include those of Col. Henry C. Chenault, executive officer, who has been named director of professional services, Col. Oliver K. Niess, base surgeon and commanding officer of the Regional State Hospital, Mitchel Field, N. Y., who has been named director of administration, and Col. Richard L. Meiling, who will act as special assistant to the Air Surgeon.

The reorganization places the Director of Administration over the Operations, Personnel and Supply Divisions, while the Director of Professional Services will supervise the Professional, Aviation Medicine, Convalescent Training, Research and Statistics Division. Two divisions have received new designations. The Medical Services Division will be called the Professional Division, and the former Professional Division will be known as the Aviation Medicine Division.

The status of the division chiefs remains unchanged. The chiefs are Col. George L. Ball, Aviation Medicine Division; Col. Howard A. Rusk, Convalescent Training Division; Col. George F. Baier III, Operations Division; Col. E. L. Gann, Personnel Division; Col. William P. Holbrook, Professional Division; Col. Lloyd E. Griffiths, Research Division; Col. Joseph Berkson, Statistics Division; Col. Gustave E. Ledfors, Supply Division, and Major William H. Perkins, Office Services.

36TH GENERAL HOSPITAL UNIT COMMENDED

The 36th General Hospital unit, organized under the auspices of the Wayne University College of Medicine, Detroit, and staffed by Detroit and Michigan men and women, has been commended by the commanding officer of Headquarters Peninsular Base Section in Italy. The 36th General Hospital was stationed at Naples during the early months of the Italian campaign. The quarters it occupied, however, have now been returned to Italian civilians, and the unit, recently detached from the Peninsular Base Section, expects immediate assignment to another war area. Dr. Edgar H. Norris, dean of Wayne University College of Medicine, made this information public on receipt of a letter from Lieut. Col. Wynan C. C. Cole, formerly of Detroit, who is medical director of the 36th General Hospital. The commendation, dated August 16, came to Colonel Cole from Col. Richard T. Arnest, surgeon, Headquarters Peninsular Base Section, and read as follows:

"Upon the separation of your organization from the Peninsular Base Section I wish to express to you, your officers, nurses and enlisted personnel my sincere appreciation of the excellent performance of your various duties while assigned to this base.

"It has indeed been a pleasure to have your organization with this command and I regret your separation from the Peninsular Base Section. The professional ability and untiring devotion to duty of the members of your organization have done much to add to the comfort and well being of casualties admitted to your hospital. You should each be justly proud of a task well done."

The 36th General Hospital unit has been overseas for eighteen months. It was organized under the auspices of Wayne University College of Medicine by authority of the Secretary of War, and its roster includes 52 physicians, 105 nurses and about 500 enlisted personnel. Virtually all of these are from Detroit and Michigan.

REGISTRY OF VETERINARY PATHOLOGY ESTABLISHED

Recently an arrangement was approved by the Surgeon General of the U. S. Army and the board of governors of the American Veterinary Medical Association for the establishment and maintenance at the Army Institute of Pathology, Army Medical Museum, Washington, D. C., of a Registry of Veterinary Pathology. This registry will become a unit of the American Registry of Pathology, an organization operating by the authority of the Surgeon General under the sponsorship of the National Research Council. Material submitted should be addressed to Director, Army Institute of Pathology, Army Medical Museum (attention Registry of Veterinary Pathology), 7th and Independence Avenue S.W., Washington 25, D. C. The director will be glad to furnish further instructions to contributors for submission of material to the Registry of Veterinary Pathology. The members of the Special Committee on Registry of Veterinary Pathology are W. H. Feldman, Mayo Foundation, chairman; Capt. Charles L. Davis, V. C., Army Institute of Pathology; Harry W. Schoening, chief, Pathological Division, U. S. Bureau of Animal Industry, and, member ex officio, Lieut. Col. Balduin Lucké, M. C., deputy director, Army Institute of Pathology.

WHOLE BLOOD SHIPPED TO FRANCE

The first shipment of whole blood from the United States to soldiers wounded in France was made by the U. S. Army Medical Department by an army plane, August 21. Daily shipments have been made since, 250 pints a day the first week and 500 pints a day the second week; 750 pints a day will be shipped soon. Type O blood is being collected by the Red Cross for the shipments in response to appeals from Major Gen. Norman T. Kirk, Surgeon General of the Army, and Rear Admiral Ross T. McIntyre, Surgeon General of the Navy. The whole blood is prepared for shipment on the day it is drawn, and twenty-one hours after it leaves the United States it is available for transfusion in France. Brig. Gen. F. W. Rankin and Col. B. N. Carter of the Surgical Consultant Division with Lieut. Col. Douglas B. Kendrick, consultant to the Surgeon General on transfusions and plasma, developed the program for the Army Medical Department, and new developments in the preservation and refrigeration of whole blood were worked out to make the plan effective.

ARMY AWARDS AND COMMENDATIONS

Major Henry T. Earhart

The Bronze Star Medal was recently awarded to Major Henry T. Earhart, formerly of Mulberry, Ind. The citation accompanying the award read "At Hollandia, Dutch New Guinea, from April 26 to May 18, 1944 he was outstanding in performance of duty in a place of great responsibility as surgeon of a signal battalion. By his conspicuous efficiency above and beyond the regular call of duty he rendered invaluable service in the handling of the sick, injured and wounded men from a command of over 600 men, with a very limited number of Medical Department personnel." Dr. Earhart graduated from Indiana University School of Medicine, Indianapolis, in 1939 and entered the service March 21, 1941.

Colonel Edgar C. Jones

The Legion of Merit Award was recently presented to Col. Edgar C. Jones, McConnelville, Ohio, for "service as assistant surgeon, Fifth Corps Area, surgeon, Fifth Corps Area, and later as chief of the Medical Branch and Surgeon Fifth Service

Command, during a period of expansion and reorganization from Oct. 22, 1940 to June 30, 1944. In the performance of his duties he displayed in the highest degree the qualities of intelligence, loyalty, devotion to duty, sound judgment and a thorough understanding of his mission. His contribution to the war effort has been a most effective one, rendered always with a most unselfish devotion to the Nation's welfare." Dr. Jones graduated from Jefferson Medical College of Philadelphia in 1906. He was in the regular army of the United States until Oct. 31, 1938, when he retired and returned to active duty Oct. 21, 1940.

Captain Emile G. Schuster

The Distinguished Service Cross was recently awarded to Capt. Emile G. Schuster, formerly of Oakland, Calif. The citation accompanying the award read "During the capture and defense of hill positions of Mount Patano, Italy, from Nov. 29 to Dec. 3, 1943 he gave medical aid to the wounded while under mortar and artillery fire and at times under direct machine gun and rifle fire. On one occasion he advanced in front of forward position under fire to an enemy mine field and rendered his services to men wounded by antipersonnel mines. During daylight hours he administered plasma in the midst of enemy fire. On one occasion while performing this task the flask was shot from his hand and the tree beside him cut down by machine gun fire. However, he secured more supplies and calmly continued his treatment. His fearless actions under

enemy fire alleviated much suffering and saved many lives." Dr. Schuster graduated from McGill University Faculty of Medicine, Montreal, in 1940 and entered the service April 6, 1942.

Colonel Alfonso M. Libasci

The Legion of Merit Award was recently given to Col. Alfonso M. Libasci, formerly of Brooklyn, for his "resourcefulness, perseverance and ingenuity" in organizing and directing the medical supply system of the Army in the Southwest Pacific area. He was cited for his achievement in organizing a supply system by means of which medical goods were swiftly and automatically routed to combat areas. He was also credited with simplifying the accounting and requisitioning systems and with developing the portable surgical hospital unit, which saved many lives in the South Pacific island jungles. Dr. Libasci graduated from Long Island College of Medicine, Brooklyn, in 1931 and has been on active duty with the Army since 1933.

Colonel Ashley W. Oughterson

The Legion of Merit was recently awarded to Col. Ashley W. Oughterson, formerly associate professor of surgery at Yale University School of Medicine, New Haven, Conn., for "exceptionally meritorious conduct in the performance of outstanding services in the South Pacific area from Dec. 1, 1942 to June 13, 1944. Dr. Oughterson graduated from Harvard Medical School, Boston, in 1924 and entered the service in January 1942.

NAVY

NAVY AWARDS AND COMMENDATIONS

Lieutenant Samuel E. Elmore Jr.

The Silver Star Medal was recently awarded to Lieut. Samuel E. Elmore Jr., formerly of New Orleans. The citation accompanying the award read "For conspicuous gallantry and intrepidity while attached to the Third Marine Division during the landing attack at Cape Torokina, Solomon Islands, on Nov. 1, 1943. When the fighting was most desperate and many of our wounded were lying helpless within dangerous proximity to the enemy, Lieutenant Elmore unhesitatingly entered the area of the Japanese defensive position and gave expert medical attention to the injured despite an incessant rain of enemy fire. While engaged in this vital work, he was suddenly and viciously attacked by a Japanese soldier and, mindful of the need for uninterrupted medical care, engaged the enemy in hand to hand combat, killing him and thereby removing an imminent threat to the lives of the men who depended on his assistance. The professional skill and outstanding valor displayed by Lieutenant Elmore throughout this engagement inspired courage and confidence among the wounded and were in keeping with the highest traditions of the United States Naval Service." Dr. Elmore graduated from Harvard Medical School, Boston, in 1940 and entered the service in September 1942.

Commander James J. Saperó

The Distinguished Service Medal was recently presented to Comdr. James J. Saperó, now on temporary duty in the Bureau of Medicine and Surgery, Navy Department, Washington, D. C. The citation accompanying the award read "For exceptionally meritorious service to the government of the United States in a duty of great responsibility while serving as malaria and epidemic disease control officer on the staff of the commander, South Pacific Area and South Pacific Force, from Aug. 17, 1942 to Jan. 2, 1944. Displaying exceptional medical skill and distinctive leadership, Commander Saperó conceived and developed the malaria control unit in the area and, as a result of his untiring efforts and those of his organization, the incidence of malaria among the military and naval forces was drastically reduced. The excellent principles and methods established by Commander Saperó in the control of this disease prevented a tremendous loss of manpower and served as a guide for checking the epidemic in other military areas. His brilliant initiative and outstanding ability contributed materially

to the superb physical conditions and high morale of our fighting forces in this vital area." Dr. Saperó graduated from Stanford University School of Medicine, San Francisco, in 1932. He has been in the service since June 1931.

Lieutenant Arthur T. Willetts

Lieut. Arthur T. Willetts, formerly of Verona, Pa., was recently awarded the Silver Star Medal "for conspicuous gallantry and intrepidity as battalion surgeon attached to the Third Marine Division during the landing attack at Cape Torokina, Solomon Islands, on Nov. 1, 1943. On finding that perilous enemy fire was endangering the lives of our wounded men who had fallen on the beachhead, Lieutenant Willetts promptly requested a nearby assault unit to attack an adjacent enemy infested jungle area and, after the site was cleared of hostile troops, established an aid station in order to attend the injured men under cover of the jungle growth. Although his medical post was attacked by enemy machine guns six times during the day, he skilfully treated many serious wounds, consistently maintaining a calm courage which concealed from the patients under his care the danger of their situation. Lieutenant Willetts' professional ability and heroic devotion to duty were in keeping with the highest traditions of the United States Naval Service." Dr. Willetts graduated from the University of Pittsburgh School of Medicine in 1937 and entered the service March 9, 1942.

EXHIBIT OF NAVAL MEDICINE AT NATIONAL GALLERY OF ART

A collection of one hundred paintings and drawings of naval medicine were put on view at the National Gallery of Art, Washington, D. C., September 10, where it will remain until October 8, after which the collection will be sent on tour throughout the United States. The artists who participated in the program and the phases of naval medicine which they covered are as follows: Hospital Corps Training, depicted by David Stone Martin and Irwin Hoffman at the Navy Medical Field Service School, Camp Lejeune, North Carolina; Combat Action, depicted by Joseph Hirsch and Kerr Eby at Pearl Harbor, New Caledonia, New Guinea, Guadalcanal, Tarawa and Bougainville; and Treatment of Convalescents, depicted by Carlos Andreson and Julian Levy at the U. S. Naval Hospital, Portsmouth, Va., and National Naval Medical Center, Bethesda, Md.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

At Rhoads General Hospital, Utica, N. Y., in conjunction with the Oneida County Medical Society: War Wounds of the Extremities: Clinical Demonstration, Major Robert Perlman, October 10.

At Camp McCoy, Wisconsin: Symposium on Organic Neurology, Dr. T. C. Erickson, October 4; Dermatologic Diseases, Dr. G. A. Cooper, October 18.

At Truax Field, Wisconsin: Endocrinology, Dr. Elmer L. Sevringhaus, October 4; Virus and Rickettsial Diseases, Dr. Marcos Fernan-Nunez, October 18.

In Canada the Committee on Wartime Graduate Medical Meetings is cooperating in the presentation of the Dalhousie Refresher Course, Halifax, Nova Scotia, from October 9 to 13, by sending the following guest speakers, who besides conducting clinics will present two scientific papers: "Gout" and "Diagnosis of Adrenal Insufficiency," Dr. George W. Thorn; "Cancer of the Prostate" and "Sex Hormones in Clinical Practice," Dr. Charles Huggins; "Tuberculosis in Children" and "Blood Dyscrasias," Dr. Ralph Tyson; "The Recognition and Management of the Psychoneurotic Patient" and "Some Common Psychosomatic Disturbances and Their Treatment," Dr. Thomas A. C. Rennie.

AMERICAN PHARMACEUTICAL ASSOCIATION
RECEIVES AWARD FOR
QUININE POOL

The War Production Board recently awarded a scroll of appreciation to the American Pharmaceutical Association on behalf of the nation's pharmacists in contributing their quinine stocks to a national pool for the armed forces. In gratitude for the more than 152,000 ounces of cinchona products collected, the government officials expressed "thanks to the pharmacists of America whose contributions made a success of the quinine pool, to the Philadelphia College of Pharmacy and Science, which first inaugurated and proved the feasibility of the pool within the commonwealth of Pennsylvania, to the personnel of the Institute of Pharmacy and to the American Pharmaceutical Association, which assumed the burden of the nationwide effort and carried it through to a commendable conclusion."

The presentation was made at the American Institute of Pharmacy by two pharmacists of the War Production Board, Fred J. Stock, chief of the Drugs and Cosmetics Branch of the Chemicals Bureau, and Henry W. Heine, chief of the Botanicals and Imports Unit of the Drugs and Cosmetics Branch of the Chemicals Bureau. The pharmacists were co-signers of the scroll with Donald M. Nelson, chairman of the War Production Board.

NEW BRITAIN GENERAL HOSPITAL
LENDs PATHOLOGIST TO U. S.

Dr. H. Weston Benjamin, managing director of New Britain General Hospital, New Britain, Conn., recently announced that the board of directors acceded to a request from the Office of Scientific Research and Development Committee on Medical Research for the services of Dr. Paul D. Rosahn, pathologist in charge of laboratories at the hospital. Dr. Rosahn will act as technical aide to the committee assigned to contracts in venereal disease under the direction of the deputy division chief in charge, Dr. Joseph Earle Moore of Johns Hopkins Hospital and University. His work is primarily the supervision of studies of the effect of penicillin in syphilis now in progress under the O. S. R. D. auspices at the request of the armed forces. He will also have certain other duties in connection with the contracts entered into between the Office of Scientific Research and Development Committee on Medical Research and various universities dealing with other research problems in the field of venereal disease. Dr. Rosahn will continue to be in charge of the laboratories at New Britain General Hospital but will spend part of each week in Baltimore, Washington,

New Britain and other cities where his duties associated with this new project may call him. During his absence from the hospital Dr. M. C. Winternitz, professor of pathology at Yale University, will work with Dr. Rosahn in supervising the pathologic and laboratory routines of the hospital.

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in *THE JOURNAL*, September 9, page 109)

ALABAMA

Children's Hospital, Birmingham. Capacity, 50; admissions, 1,329. Mrs. Victoria K. Willman, R.N., Superintendent (resident—pediatrics).

CALIFORNIA

St. Luke's Hospital, San Francisco. Capacity, 225; admissions, 6,678. Dr. Howard H. Johnson, Medical Director (1 intern).

ILLINOIS

St. Joseph's Hospital, Joliet. Capacity, 334; admissions, 7,354. Sister M. Henrica, R.N., Superintendent (interns).

KENTUCKY

St. Elizabeth Hospital, Covington. Capacity, 367; admissions, 5,938. Sister M. Alacoeque, Administrator (1 intern).
Louisville General Hospital, Louisville. Capacity, 587; admissions, 9,805. Dr. John Walker Moore, Medical Director (1 resident—medicine; 1 intern).

MARYLAND

Johns Hopkins Hospital, Baltimore. Capacity, 1,034; admissions, 17,699. Dr. Winford H. Smith, Medical Director (1 assistant resident, 1 resident—roentgenology).

MICHIGAN

Charles Godwin Jennings Hospital, Detroit. Capacity, 108; admissions, 2,304 (3 interns, Nov. 1, 1944; 3 interns, July 1, 1945).

MINNESOTA

St. Mary's Hospital, Duluth. Capacity, 320; admissions, 9,474. Sister M. Patricia, Superintendent (interns).
St. Mary's Hospital, Minneapolis. Capacity, 340; admissions, 10,702. Sister Conchessa, Superintendent (interns).
Bethesda Hospital, St. Paul. Capacity, 180; admissions, 6,083. Rev. L. B. Benson, Superintendent (interns).
St. Joseph's Hospital, St. Paul. Capacity, 308; admissions, 10,335. Sister M. Ignatius, R.N., Superintendent (interns).

OPEN PSYCHIATRIC REHABILITATION
CLINIC AT MOUNT ZION
HOSPITAL

A psychiatric rehabilitation clinic for the treatment of ex-servicemen and women discharged from the armed forces on account of neuropsychiatric disabilities has been established at the Mount Zion Hospital, San Francisco. The clinic will utilize both individual and group therapy and will be staffed by psychiatrists, internists, psychiatric social workers, vocational advisers and dietitians. It will be open both during the day and in the evening for the benefit of men and women who are employed in industry. A close contact will be maintained with the United States Army and Navy hospitals, the Red Cross, the United States War Manpower Commission, the State Bureau of Vocational Rehabilitation and the various social agencies of the city of San Francisco. The project was made possible by a grant from the Columbia Foundation of San Francisco. Dr. J. S. Kasanin is director of the clinic.

MERCY SHIPS

Three Netherlands liners, specially converted for the purpose, are being used as hospital ships to evacuate American wounded from the northern Netherlands New Guinea coast to base hospitals. The ships, whose white hulls have become familiar sights along the invasion beaches, are the *Maatsuycker*, the *Abel Tasman* and the *Jansen*.

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

Sept. 11, 1944.

Hearings on Poliomyelitis

Use of the airplane to evacuate victims of infantile paralysis in sparsely settled states like Nevada and Wyoming is recommended by Dr. Frank R. Ober of Boston, professor of orthopedic surgery at Harvard Medical School. Dr. Ober told the Kelley committee investigating aid to the physically handicapped that excellent work is being done throughout the country in rehabilitation of patients with infantile paralysis. The war had created difficulty in getting orthopedic surgeons, but, when hostilities cease, surgeons now in the Army will be available to carry on the work more successfully, he said. Lack of publicity was one reason for failure of people to take full advantage of facilities now in existence for treatment of the disease. While expressing the view that adequate clinical facilities were now operating in such states as Massachusetts, New York and Pennsylvania, Dr. Ober admitted that sparsely settled sections are without adequate means for treatment of the disease. Asked if he thought regional clinics should be set up, he said "It seems to be that is the way to take care of it." In the early stages of poliomyelitis, Dr. Ober said, nursing is required to relieve the painful symptoms and to prevent deformities. After painful symptoms have disappeared, active methods must be applied toward restitution of the functions and improvement of muscles, which is done by physical therapy, under direction of a physician who understands the problems. Rehabilitation is complicated by the fact that treatment may be required indefinitely. Maximum recovery is within twelve to twenty-five months, yet he had seen recovery take place after thirty-five years. Dr. Ober described in detail the organizations that had been set up in Vermont and Massachusetts for the physically handicapped.

Other witnesses at the hearings on poliomyelitis were Dr. Charles Armstrong, chief of the Division of Infectious Disease, U. S. Public Health Service, Dr. A. L. Van Horn, director of the Division of Health Services, Children's Bureau, Department of Labor, and Dr. Don W. Gudakunst, medical director of the National Foundation for Infantile Paralysis.

Samuel Barker, general counsel for the committee headed by Augustine B. Kelley (Democrat, Pennsylvania) on the physically handicapped, said hearings would continue September 12 to 14 on problems of the deaf and hard of hearing.

\$10,000,000 Asked for Infantile Paralysis Study

A resolution authorizing the expenditure of \$10,000,000 for the study of the causes and cure of infantile paralysis has been proposed for immediate consideration by Senator Langer (Republican, North Dakota). Author of the measure, which he introduced because of the unusual prevalence of the disease in the Eastern states this year, particularly in the District of Columbia and nearby communities, Senator Langer stated that he would urge Senator Thomas (Democrat, Utah) to call a meeting of the Education and Labor Committee to get action if possible before the impending recess of Congress.

Wartime Health Program Hearings Resume

Health needs of veterans will be one of the subjects to be investigated when the second series of public hearings on the National Wartime Health Program resume September 18, 19 and 20, Senator Claude Pepper (Democrat, Florida) announced today. He is chairman of the Senate Special Subcommittee on Wartime Health and Education. Other topics to be taken up are the significance of the Selective Service physical examination data, methods of improving the distribution and quality of medical care, hospital planning and construction. "At the first series of hearings," said Senator Pepper, "the committee heard testimony of medical and dental experts of the Army, Navy, Selective Service System and U. S. Public Health Service. Startling data were disclosed relating to the tragic fact that

nearly 5,000,000 of the nation's young men have been found physically and mentally unfit for service in the armed forces of their country. Constructive proposals have been offered to improve the people's health so that in the future, whether in war or in peace, the nation will not be similarly handicapped."

Senator Pepper indicated that at the September 18-20 hearings representatives of the organized medical profession, industry and labor will testify. Witnesses will include Dr. Roger I. Lee, President-Elect, Dr. Harvey Stone and Dr. R. L. Sensenich of the American Medical Association; Dr. John P. Peters, secretary, Committee of Physicians for Improvement of Medical Care; Dr. E. I. Robinson, president, National Medical Association; Dr. Ernst P. Boas, chairman, Physicians Forum; Dr. John R. Boling, president, Florida State Medical Society; Dr. Victor Heiser, chief medical consultant, National Association of Manufacturers; Dr. Leverett D. Bristol, chairman, Health Advisory Council, U. S. Chamber of Commerce, and representatives of the American Federation of Labor and the Congress of Industrial Organizations. Mayor Fiorello H. LaGuardia will testify concerning the projected health insurance plan for New York City.

Venereal Disease Problem

A national conference on venereal disease control will be held in St. Louis, November 9 to 11, Dr. J. R. Heller Jr., chief of the Venereal Disease Division of the U. S. Public Health Service, has announced. "The war has brought large increases in venereal disease infections in many parts of the world," he said. "Simultaneously, however, science has produced new drugs, and medical research has produced new methods to combat syphilis and gonorrhea. A major purpose of the conference will be to consider how these new methods can be applied promptly on the large scale necessary to halt what might become a worldwide postwar venereal disease epidemic.

"The seriousness of the venereal disease problem throughout the world," he said, "is exemplified by reports indicating that infections are spreading even in the Scandinavian countries, which for many years have been almost free of venereal disease." Dr. Heller said that with millions of Americans returning from foreign lands, and an enormous expected increase in travel to and from the United States, effective venereal disease control will require international cooperation. The eighth postgraduate course in venereal disease control will be conducted at the Public Health Service Medical Center, Hot Springs, Ark., October 19 to November 8. The postgraduate training course will be given to health officers and to private physicians cooperating with state and local health department venereal disease control programs.

Dr. Heller, in a letter to venereal disease control workers, said that an enormous new venereal disease control responsibility will face state and local health departments throughout the country on demobilization. He said that a plan had been agreed on by the Surgeon General of the Army and the Surgeon General of the Public Health Service which would assure return of soldiers to civilian life practically free of infectious syphilis "and thus preclude the introduction of new chains of infections in home communities." The plan is already in operation at army separation centers and will be used when large scale demobilization begins.

Social Hygiene Instruction in Schools

A program of social hygiene instruction in public schools "to begin with the preschool child, continue throughout public school training and carry over into the education of adults, particularly parents," is recommended in a resolution of the board of managers of the National Congress of Parents and Teachers. Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, was advised that the congress supports the efforts of federal, state and local educational authorities to institute such a program. The congress believes that the program will help

in "providing adequate juvenile protection, preventing the spread of venereal infection and providing more adequate personal, family and community living."

Music as an Aid to Treatment

Music as an adjunct to medicine is being tried out at Walter Reed General Hospital here. The Surgeon General of the United States Army has authorized the Institute of Applied Music to conduct an experiment in developing the potentialities of music in relation to medicine. The institute, a group of professional musicians, was organized to work out the problem on patients to determine the effect of music on certain types of mental and nervous disorders. The group is engaged in the experiment under the guidance of Miss Frances Paperte, former member of the Chicago Opera Company and soloist with the New York Philharmonic and Cincinnati symphony orchestras. Participating musicians are working in close collaboration with army psychiatrists treating the patients. The institute plans to learn how the slightest gain, if any, is accomplished, to determine if it will work again and if it can be accepted as a rule. All music presented will be checked against a table of variables and applied in a predetermined manner, subject to the requirements of the doctor in charge. Probability curves have been charted, and these will be checked against actual results obtained. From this, greater refinements can be plotted, until cause and effect principles have been established.

"As in any scientifically controlled experiment," says Miss Paperte, "it is obvious that it must be proved beyond any doubt that the system followed is dependable. The work, of course, is too new to permit of conclusions. Various methods have been explored and at present it may be safe to say that indications are encouraging." She said that music as an aid to treatment has been tried before, but it has never been properly or adequately controlled, nor has its application been evaluated

scientifically. The music itself, presented by the highest type of professional musicians, is regarded solely as an aid to treatment and not, as popularly regarded, as merely an entertainment or recreational performance. Miss Paperte states that most people are unaware of the deep understanding required in considering the psychologic significance of music as utilized in the work. Dealing with the instinctive tendencies of human beings is a serious matter, with physical, psychologic and social values at stake, and these factors are too significant to allow of any but technically sound and objective handling.

FWA Grants Washington Hospitals \$4,100,000

The Federal Works Administration grant of \$4,100,000 to George Washington and Georgetown universities for two new 400 bed hospitals in the capital may obviate necessity for the proposed 1,500 bed medical center, according to Representative Thomas D'Alesandro Jr. (Democrat, Maryland). He expressed the hope that grants would also be made to Gallinger, Providence and Emergency hospitals. The FWA grants came as a result of congressional activity to increase Washington's badly needed hospital facilities. Construction is to start soon, and the two hospitals should be ready for occupancy in a year. Order for allocation of funds has been signed by President Roosevelt, and priorities have been approved. Georgetown University was granted \$1,400,000 for a building to be erected on a university owned site on Reservoir Road. The university will furnish \$600,000 in funds to replace its old buildings of 265 bed capacity, some 50 years old. George Washington University was granted \$2,700,000 for construction of a nine story building and purchase of a site near Washington Circle. The university will post \$350,000 for the project and pay the government money derived from sale of its present 92 bed building. Abandonment of the universities' present hospital buildings will mean a net gain of 443 new hospital beds for the District of Columbia.

MEDICAL ECONOMIC ABSTRACTS

THE MILWAUKEE MEDICAL SOCIETY EXPANDS PREPAYMENT PLAN

According to reports in the *Milwaukee Journal and Sentinel* the Milwaukee Medical Society has decided to expand a plan which it has had in operation for the last seven months for the 300 employees of one company into a general plan to be offered to all industrial organizations. Only surgical and obstetric care in a hospital will be covered.

The monthly rates charged are for the individual \$0.90, for husband and wife, including maternity, \$1.75, and for the complete family \$2.50. While it is expected that most enrolments will be through pay roll deductions, arrangements will be made for other groups where possible. The income limit for an individual is \$1,800 a year and for a family \$2,400, plus \$200 for each child under 18. For subscribers above this income the indemnity plan will be used with the physician entitled to make an additional charge if desirable.

CHANGES IN NEW JERSEY PLAN CONTRACT

The Medical-Surgical Plan of New Jersey has revised its contract, making it possible for physicians to make additional charges under the following conditions:¹

If the patient shall have been admitted to a hospital for a private accommodation not exceeding one bed per room.

If the patient shall have been admitted for semiprivate or ward accommodations and shall have agreed to pay the participating physician an additional amount; except that additional amounts shall not be payable if under the "single contract" the annual income of the subscriber is less than \$2,000 or under the "family contract" the annual income of the subscriber is less than \$2,000 plus \$500 for the first enrolled dependent plus \$250 for each additional enrolled dependent.

If the income of the subscriber is more than that stated in the preceding paragraph but he has failed to divulge the existence of the contract to the physician.

The amounts payable for obstetric care shall not be considered as including payment for antepartum and postpartum care rendered outside the hospital.

Amounts payable by the plan will be paid for obstetric deliveries occurring in the home or elsewhere outside the hospital under conditions beyond the control of the patient.

Services rendered at the time of full term obstetric deliveries or for tonsillectomies will not be eligible for payment unless rendered at least nine months after the effective date of the subscriber's contract.

Amounts up to \$25 will be payable for emergency services rendered in caring for accidental injuries which would ordinarily be hospitalized, if services are rendered in outpatient departments or elsewhere outside the hospital, provided the services are rendered within twenty-four hours of the accident.

Medical services (not surgical) eligible for payment will be limited to such services rendered during twenty-one days of hospitalization during any one contract year.

PREPAYMENT PLAN IN GEORGIA

According to the bulletin of the Fulton County (Ga.) Medical Society for June 1 the Fulton County society presented a skeleton plan for medical and surgical care to the house of delegates of the Medical Association of Georgia at its recent meeting. The plan provided that the control be vested in the Medical Association of Georgia and was favored by the reference committee and adopted by the association.

According to the bulletin, "Voluntary health plans of other states will be studied and the cooperation of state, county and municipal authorities solicited in the formation of a workable pattern to assure the people of our state better distribution and accessibility of medical and surgical care and adequate hospitalization."

1. J. M. Soc. New Jersey 41: 316 (Aug.) 1944.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Psychiatric Rehabilitation Clinic.—The department of psychiatry of the Mount Zion Hospital of San Francisco has opened a psychiatric rehabilitation clinic for the treatment of ex-servicemen and women discharged from the armed forces because of neuropsychiatric disabilities.

Surcharge Over Existing Industrial Accident Fees.—The state industrial accident commission has approved a surcharge of 15 per cent over existing industrial accident fees, effective August 1. The surcharge will be effective for the duration of the war. According to the *Bulletin* of the Los Angeles County Medical Association, the commission proposes to establish a study committee to consider "a permanent medical fee schedule to become effective after the 'duration.'" The commission has had under consideration for some time a proposed schedule of medical and surgical fees for some 547 procedures which might be undertaken in compensation work. While the proposed schedule has not been approved, the surcharge of 15 per cent for existing fees was approved. The provision covering the surcharge states that "cases under treatment before and after Aug. 1, 1944 shall have their medical and surgical charges segregated, so that services rendered before Aug. 1, 1944 shall be charged at the existing rates and services rendered after August 1 shall be billed at existing rates plus the 15 per cent surcharge."

DISTRICT OF COLUMBIA

Personal.—Sir Howard Walter Florey, professor of pathology at the University of Oxford, England, who is largely concerned with the development of penicillin and its use, visited Washington during the first week in August.—Dr. J. Winthrop Peabody, Washington, has been elected an honorary member of the Sociedad Chilena de Tisiologia.

ILLINOIS

Society News.—Dr. Alexander J. Kotkis, St. Louis, discussed "Some Problems of Physical Medicine in the Field of Therapeutics" before the Madison County Medical Society in Granite City, September 1.

Chicago

Food in International Relations.—The twentieth annual institute of the Norman Wait Harris Memorial Foundation was held at the University of Chicago, September 4-8. The theme of the meeting was "Food in International Relations" and speakers included Conrad A. Elvehjem, Ph.D., Madison, Wis.; Karl Brandt, Dr. Agr., Stanford University, Calif., and Paul H. Appleby, LL.D., assistant director of the Bureau of the Budget, Washington, D. C. Among other speakers at the meeting were Dr. Frank G. Boudreau, chairman of the food and nutrition board, National Research Council; John D. Black, Ph.D., Harvard University, Cambridge, Mass.; Dr. Andrew C. Ivy, head of the department of physiology and pharmacology, Northwestern University Medical School; Dr. Paul R. Cannon, chairman of the department of pathology, University of Chicago School of Medicine; Leonard A. Maynard, Ph.D., School of Nutrition, Cornell University, Ithaca, N. Y., and Ancel B. Keys, Ph.D., University of Minnesota, Minneapolis.

KANSAS

New Secretary of Sedgwick County.—Mr. Martin Baker, Wichita, formerly instructor in music at the Wichita North High School, has been chosen executive secretary of the Sedgwick County Medical Society. He fills the vacancy that occurred when Mr. Oliver Ebel resigned to become executive secretary of the Kansas Medical Society.

New Building for Research in Psychiatry.—On July 24 the Menninger Foundation opened a new building for research and education in psychiatry at 3614 West Sixth Avenue, Topeka. The new building has twenty-five rooms, including soundproof laboratories, class rooms and offices and a large conference room, and houses the work of the research, teaching

and administrative departments of the foundation. The educational work of the foundation consists at present in the teaching of resident physicians in psychiatry, the postgraduate training of nurses and the teaching of psychologists, therapists and psychiatric social workers. Plans are being completed for postwar instruction of physicians in psychosomatic medicine. The Menninger Foundation was established in 1942 as a non-profit organization to advance research and education in neuropsychiatry. It announces the publication soon of the results of a three year research project on the "Validation and Evaluation of Psychological Testing Techniques." This will be the second report of the foundation's research project to appear in book form, the first being a monograph entitled "Emotions and Memory." Among projects under way at the present time are "An Investigation of the Applications of Hypnosis in Modern Psychiatry" and "An Investigation of the Clinical Syndrome of Firesetting." A preliminary report of the former was presented at the 1944 session of the American Psychiatric Association.

KENTUCKY

Personal.—Dr. William J. Walter, Pikeville, has been appointed director of the Pike County Health Department.

State Medical Meeting in Lexington.—The Kentucky State Medical Association has designated its 1944 meeting at the Phoenix Hotel, Lexington, September 18-20, the Benjamin Rush Palmer Memorial Meeting in honor of the ninth president of the association, who served from 1860 to his death in 1865. The meeting will be under the presidency of Dr. James H. Pritchett, Louisville. Speakers will include:

Dr. John A. Toomey, Cleveland, Chemotherapeutics in Pediatrics.
Dr. Maurice Levine, Cincinnati, Psychosomatic Medicine.
Col. Anthony J. Lanza, M. C., Present Status of Industrial Medicine.
Major Gen. David N. W. Grant, M. C., Current Problems in Aviation Medicine.
Dr. Frederick H. Falls, Chicago, The Present Status of Pain Relief in Labor.
Dr. William D. Stroud, Philadelphia, Cardiovascular Diseases.
Dr. Ralph Pemberton, Philadelphia, Arthritis.
Brig. Gen. Fred W. Rankin, M. C., Medical Service in a Theater of War.
Dr. Irvin Abell, Louisville, Surgical Aspects of the Chronic Dyspepsia.
Col. John B. Youmans, M. C., Nutrition—Its Relation to Deficiency Diseases.

The oration in medicine will be delivered Tuesday by Dr. Frederick G. Spidel, Louisville, on "Conservatism and Liberalism in Medicine" and the oration in surgery Wednesday by Dr. James Farra Van Meter, Lexington, on "Penicillin—An Early Evaluation in Surgical Complications." A public meeting will be held Tuesday evening in the auditorium of the U. S. Public Health Service Hospital, at which the speakers will include Drs. Oscar O. Miller, Louisville, president-elect of the state society, on "Some Aspects of the Tuberculosis Problem"; Roger I. Lee, Boston, President-Elect of the American Medical Association, "Accelerated Medicine Today and Tomorrow," and Edward H. Cary, Dallas, "The Medical Profession and Federal Legislation." One session will be devoted to chemotherapy (penicillin), the civilian aspect to be presented by Dr. Donald G. Anderson, Boston; medical aspects, Brig. Gen. Hugh J. Morgan, M. C.; surgical aspects, Col. Burr N. Carter, M. C., and venereal disease treatment by Lieut. Col. Thomas H. Sternberg, M. C. There will be a symposium on tropical diseases Wednesday at which the speakers will be Rolla E. Dyer, assistant surgeon general, U. S. Public Health Service, Capt. Alphonse McMahon (MC), and Brig. Gen. James S. Simmons, M. C. The twenty-second annual meeting of the Woman's Auxiliary to the state medical association will be held at the Lafayette Hotel, Lexington, September 18-20.

MICHIGAN

State Medical Meeting in Grand Rapids.—The seventy-ninth annual session of the Michigan State Medical Society will be a postgraduate conference on war medicine at the Civic Auditorium and the Pantlind Hotel, Grand Rapids, September 27-29, under the presidency of Dr. Claude R. Keyport, Grayling. Included among the speakers will be:

Dr. Geza de Takats, Chicago, Vascular Disease.
Dr. Earl D. Osborne, Buffalo, The Treatment of Eczema (Dermatitis).
Based on Etiology.
Dr. Robert A. Moore and Edward Mallinckrodt Jr., St. Louis, The Pathology of Rickettsial Diseases.
Dr. John W. Harris, Madison, Wis., The Place of the General Practitioner in the Practice of Obstetrics.
Dr. Arthur W. Proetz, St. Louis, Allergy in the Ear, Nose and Throat.
Dr. Tom D. Spies, Birmingham, Ala., and Cincinnati, Vitamins and the Practice of Medicine.
Dr. Max M. Zimnitzer, Cincinnati, Gallbladder.
Dr. Albert D. Ruedemann, Cleveland, The Protruding Eye.
Dr. Joseph L. Baer, Chicago, Prolonged Labor.

Dr Emery A Rovenstine New York, The Preanesthetic Preparation of the Surgical Patient
 Dr Frank H Krusen Rochester, Minn., A Rehabilitation Program for Military Veterans
 Dr Abel A Applebaum Toledo, Ohio Primary Atypical Pneumonia
 Dr Sidney Farber, Boston, Some Organic Digestive Disturbances in Early Life (Nature, Diagnosis and Treatment)
 Dr S William Becker, Chicago, Penicillin in the Treatment of Syphilis
 Dr Arthur C Curtis Ann Arbor, Mich Recent Advances in the Treatment of Syphilis
 Dr Charles A Aldrich Rochester, A Preventive Medical Program as Applied to Pediatrics
 Dr Frederick H Tails Chicago, Obstetrical Hemorrhages
 Dr James L Wilson New York Advance in the Prevention and Treatment of Poliomyelitis

Military speakers will include

Brig Gen Charles C Hillman M C Tropical Medicine
 Capt Arthur W Frisch, M C, Sulfonamide Resistant Gonorrhea
 Major Frank H Mayfield M C, Herniated Nucleus Pulposus
 Herman E Hilleboe medical director and Eugene J Gillespie, senior assistant surgeon, U S Public Health Service, The Role of the General Practitioner in Tuberculosis Control
 Col William C Menninger, M C Neuropsychiatry and the General Practitioner Lessons Learned from the Army
 Charles J Clark, flight surgeon and Harry Britton, assistant flight surgeon, What We have Learned About Aviation Medicine
 Brig Jonathan C Meakins R C M C, What a Modern Army Health Service Should Be

On Wednesday evening Preston Bradley, LL.D., Chicago, will deliver the Andrew P Biddle Oration on "When Doctors Disagree" Thursday evening has been designated "State Society Night" and speakers will include Dr Robert L Novy, professor of clinical medicine, Wayne University College of Medicine, Detroit, and John F Hunt, executive and director of research Foote, Cone and Belding, advertising agency, Chicago, on "What the People of Michigan Think of Medicine" Features of the annual session will include a series of seventeen discussion conferences (quiz periods) covering general practice and the various specialties The county secretaries' conference will be held Wednesday evening, September 27, the speakers will be Dr L Fernald Foster, Bay City, on "The Michigan Picture in Medicine", Mr M C Smith, Lincoln, Neb., "Nebraska's New Medical Practice Act," and Dr Freeman A Brockenshire, Windsor, Ont., Canada, "Health Insurance Proposals in Canada" The Woman's Auxiliary will meet at the Panthind Hotel, September 26-28 The lecture by Dr Hilleboe is sponsored by the Michigan Tuberculosis Association The American College of Chest Physicians, Michigan chapter, and the Michigan Pathological Society will meet during the session

NEW YORK

Rheumatic Heart Disease Program—The Yonkers Tuberculosis and Health Association recently launched a program for the control and treatment of rheumatic heart disease in Yonkers, involving the establishment of a special clinic for prevention, control and study of the disease and a coordinated citywide educational project, according to the *Westchester Medical Bulletin* The clinic is to be located at St John's Riverside Hospital, Yonkers, equipped and financed by the hospital, and will include a fluoroscope, laboratory and electrocardiographic facilities The tuberculosis and health association will provide a salary for a specially trained worker who will study the work with the patients at the clinic, the home background of rheumatic children, and will assist in an advisory and teaching capacity with the nurses of the city health department, the Visiting Nurse Association and the hospital and school nurses

Report on Mental Patients—The temporary commission on state hospital problems in a recent report recommended that steps be taken to make insulin shock therapy available in the future to dementia precox patients in all state hospitals for the insane In order to obtain a consistent use of the new treatment, the commission urged that a consulting service be established in the state department of mental hygiene to assure adequate records, to hold consultations with hospital staffs and to make follow-up studies The offering of special courses to train personnel at the New York State Psychiatric Institute and Hospital also was urged The report stated that 1,128 dementia precox patients treated at the Brooklyn State Hospital "did substantially better in all respects" than 876 patients in other state hospitals in the metropolitan area who were not so treated Fifty-five per cent of the patients who were given insulin shock therapy were enabled to become useful members of the community, 79.5 per cent of the insulin treated patients were able to leave the hospital compared with 58.8 per cent of the nontreated group and after a shorter stay.

New York City

Otto Loewi Receives Cameron Prize.—Dr Otto Loewi, research professor in pharmacology at New York University College of Medicine, has been awarded the Cameron Prize in Practical Therapeutics of the University of Edinburgh in recognition of "his fundamental work on the chemical transmission of the nervous impulse," *Science* reports

Course in Industrial Medicine.—On October 31 the Medical Society of the County of Queens will initiate a series of lectures in industrial medicine The opportunities in industrial health will be discussed by Dr James G Townsend, U S Public Health Service, and Dr William A Sawyer, Rochester, N Y Ten lectures will be offered and a certificate will be issued to those who attend the sessions showing their completion of the course

Diabetes Association to Develop New Camp.—The New York Diabetes Association on August 23 announced that it had taken title to the former Golden Rule Inn property on Mirror Lake 4 miles below Kingston, N Y, and will convert the buildings into a camp for poor diabetic children of greater New York Dr George E Anderson, Brooklyn, president of the association, estimated that \$10,000 would be needed to convert the buildings to meet the requirements of a diabetic children's camp, according to the *New York Times*

Institute of Clinical Oral Pathology.—The New York Institute of Clinical Oral Pathology will hold a symposium on "Fluorine in Dental Public Health" at the New York Academy of Medicine, October 30 Included among the speakers will be

Frederick S McKay, DDS, Colorado Springs, Colo, Fluorine and Mottled Enamel A Historical Survey
 Henry Trendley Dean, senior dental surgeon, U S Public Health Service The Epidemiology of Fluorosis and Dental Caries
 Dr Wallace D Armstrong, Minneapolis, The Fluorine Content of Enamel in Relation to Resistance of Teeth to Caries
 Basil G Bibby, D M D Boston, Effects of Topical Application of Fluorides in Dental Caries
 David B Ast, DDS, Albany, N Y, The Practicability, Efficiency and Safety of Fluorinating a Communal Water Supply Deficient in Fluorine to Control Dental Caries

NORTH CAROLINA

Physician Wills Library to County Medical Society.—The will of the late Dr Charles H Cocke, Asheville, provided that his medical library, magazines and other publications be given to the Buncombe County Medical Society Library in Asheville Dr Cocke died August 3

Bennett College Extends Health Service.—A grant of \$21,310 has been given by the General Education Board to cover a three year period to the Bennett College for Women, Greensboro, to enlarge its health program According to the *New York Times* the annual home making institute held at the college has made available to a larger community results of studies in health, home and family life When the new project is set in operation in September a full time community worker will direct it, using all the resources of the college to make available the maximum facilities in personnel The program aims to give Bennett students an understanding of how a knowledge of health can function in the community and to make the community more aware of health problems.

OHIO

Bureau of Industrial Hygiene Created—The Cleveland City Health Department has created a bureau of industrial hygiene Mr Herbert G Dyktor, for more than four years chief of the new Cleveland bureau of industrial hygiene of the city of Health, Lansing, has been named

Personal—Dr Ewing H Crawfis, assistant superintendent and psychiatrist at the Lima State Hospital, Lima, has been appointed superintendent of the Cleveland State Hospital succeeding Dr Hans P Lee, who resigned to return to the Toledo State Hospital, Toledo—Dr John G Schwarz has been named superintendent at the Ohio Hospital for Epileptics, Gallipolis

Academy of Medicine Program—On September 19 the annual meeting of the Academy of Medicine of Cincinnati will open its regular season Dr Chester S Keefer, Boston, will speak October 3 on "Penicillin" Subsequent programs in the society's schedule include the following

Dr Lawrence S Kubie, New York, Psychotherapy in Medical Practice, October 17
 Dr Herbert C Maier, New York, Surgical Treatment of Pulmonary Suppuration November 7
 Dr Shields Warren, Boston The Early Diagnosis of Cancer, November 21 (joint meeting with the cancer council)

Dr. Eugene A. Stead Jr., Atlanta, Ga., Mechanism and Treatment of Shock and Circulatory Collapse, December 5 (joint meeting with the heart council).

Dr. Frederick C. Irving, Boston, Cesarean Section, December 19.
Dr. Otto K. Engelke, Ann Arbor, Mich., The Relations Between the Health Department and the Doctor, Jan. 2, 1945.
Lieut. Comdr. Alvin F. Coburn (MC), The B. K. Rachford lectures on "Therapy and Prevention of Rheumatic Fever," January 16 and 17.
Dr. Merrill C. Sosman, Boston, X-Ray Diagnosis, February 6.

The Roger Morris Lecture of the society will be delivered February 20 by Dr. George J. Heuer, New York.

OREGON

Personal.—Carlisle P. Knight, Portland, medical director of the U. S. Quarantine and Hospital Service in Oregon, was recently given a banquet in Portland on the occasion of his retirement after thirty-six years with the U. S. Public Health Service.—Dr. Lamar A. Byers, Jackson, Tenn., has been named health officer of Coos County with headquarters in Coquille.

Survey of Child Guidance Clinics.—Dr. Milton E. Kirkpatrick, director of the division on community clinics of the National Committee for Mental Hygiene, New York, will conduct a survey of community child guidance clinics in Oregon. The survey was instituted by a number of interested agencies in the state and will determine the status of the existing program in the state and particularly in the Portland area.

TEXAS

Progress of Medical Library Plans.—Tentative plans for the construction of a new medical library building in Houston include the housing under one roof of the activities of the Houston Academy of Medicine, the Harris County Medical Society, the Postgraduate Medical Assembly, the Medical and Dental Service Bureau, the *Medical Record and Annals* and the woman's auxiliary. The proposed building would be a three story construction and contain the combined libraries of the Houston Academy of Medicine, the Baylor University College of Medicine, the M. D. Anderson Foundation for Cancer Research and the Texas University College of Dentistry. In addition, there will be an auditorium accommodating about 400 persons. It is anticipated that the construction would cost around \$450,000. At a meeting, July 19, fellows of the Houston Academy of Medicine pledged their incomes for from twelve to fifteen days to assist in obtaining needed funds.

Changes in the Faculty at Texas Medical Branch.—D. Bailey Calvin, Ph.D., has been promoted to professor of biologic chemistry and associate dean at the University of Texas Medical Branch, Galveston. New appointments include:

Thurlo B. Thomas, Ph.D., appointed assistant professor of anatomy.
Dr. Wesley F. McKinley Jr. appointed assistant professor of internal medicine.

Henry J. Ralston, Ph.D., San Francisco, appointed assistant professor of physiology.

Dr. Carl U. Dernehl appointed to assistant professor of industrial hygiene in the department of preventive medicine and public health.

Promotions at the school include:

Dr. Jack R. Ewalt promoted to professor of neuropsychiatry.
Col. Robert M. Moore, M. C. (on leave for military service) promoted to professor of surgery.

Dr. Stephen Weisz promoted to associate professor of neuropsychiatry.

Dr. Julius L. Jinkins promoted to associate professor of obstetrics and gynecology.

Dr. Henry H. Sweets Jr. promoted to associate professor of pathology and director of the John Sealy Clinical Laboratory.

Major Truman G. Blocker Jr., M. C. (on leave for military service) promoted to associate professor of surgery.

Dr. A. J. Jinkins promoted to assistant professor of obstetrics and gynecology.

Dr. Norman D. Schofield promoted to assistant professor of pathology.

WASHINGTON

Personal.—Dr. Thomas H. Biggs has been appointed health officer of Kelso in addition to his work as health officer of Cowlitz County.—Dr. Joseph H. Fitz, Montesano, has resigned as county coroner of Grays Harbor.—Dr. William Ernest Rownd Jr. was recently appointed police surgeon of Bremerton.—Dr. Emil E. Palmquist, Seattle, health officer of King County, was recently elected president of the Washington State Social Hygiene Association.

WEST VIRGINIA

District Health Conference.—"Control of Tuberculosis in West Virginia" will be the theme of the annual Southern District Health Conference, covering twenty-four counties in the state, which will be held September 29 at the Daniel Boone Hotel, Charleston.

WISCONSIN

Personal.—Dr. Arthur V. de Neveu recently resigned as medical director of the Johnston Emergency Hospital, Milwaukee, to enter private practice; he held the position for eighteen years.

Kellogg Gift for Health Education.—A grant has been given by the W. K. Kellogg Foundation of Battle Creek, Mich., to be available for five years for a program of health education in Wisconsin. The fund will be administered by the Wisconsin department of public instruction, newspapers reported.

First County Mental Hygiene Program.—Brown County has made plans to employ a psychiatrist to hold a child guidance center to further mental hygiene. This action is an extension of the program that has been carried on by the Wisconsin State Board of Health for the past two years. The county is said to be the first in the state that has inaugurated a mental hygiene program. Two members of the sever member psychiatric committee of the Brown County Board of Supervisors which has set up the program are Drs. George M. Shinnors, health commissioner of Green Bay, and Marshall W. Meyer, district health officer of the state board of health.

HAWAII

Penicillin Center.—Queen's Hospital, Honolulu, has been designated as the central distributing center for penicillin for civilian use in the Territory of Hawaii. A total of 50 million units has been allotted for distribution for the first month, the order having been placed through the War Production Board as of June 15.

Health in Hawaii.—In 1942 there were 10,422 live births reported for the Territory of Hawaii. The crude birth rate was 23.6 per thousand of estimated population, as compared with the rate of 23.0 per thousand of estimated population in 1941. Of the 10,422 live births 3,754, or 36 per cent, were Japanese; 2,764, or 27 per cent, were part Hawaiian; 1,845, or 18 per cent, were Caucasian; 1,044, or 10 per cent, were Filipino; 548, or 5 per cent, were Chinese, and 246, or 2 per cent, were Hawaiian. There were 3,397 deaths from all causes in 1942, a death rate of 7.7 per thousand of estimated population. This rate is considerably lower than the rate of 12.2 per thousand of population for 1941, when war casualties from the air raid on Pearl Harbor greatly increased the crude death rate. A comparison which excludes deaths among military personnel and civilians due to operations of war in 1941 shows that the crude death rate in 1942 was slightly higher than that recorded in 1941. The ratio of births to deaths reported for the Territory of Hawaii in 1942 was 307 births to 100 deaths. This ratio has been increasing steadily in the Territory of Hawaii in recent years up to 1941, when war casualties caused a large decrease. The ratio was 253 in 1937, 281 in 1938, 299 in 1939, 305 in 1940 and 189 in 1941. There were 405 deaths of infants under 1 year of age in 1942, an infant mortality rate of 38.9 per thousand live births. This rate was 3.5 per cent lower than that for 1941 and is the lowest infant mortality rate ever recorded for the Territory of Hawaii. The rapid decline in the infant mortality rate for the Territory of Hawaii is most impressive; during the past ten years it has been practically cut in half. The six principal causes of death and their death rates in the Territory of Hawaii in 1942 were diseases of the heart 132.7, accidents other than motor vehicle 90.9, cancer and other malignant tumors 64.9, tuberculosis 62.8, nephritis 58.5 and pneumonia (all forms) and influenza 47.5 per hundred thousand estimated population. These causes accounted for more than 59.6 per cent of all deaths. Relatively large decreases in the death rate were reported in 1942 for cancer and other malignant tumors and for intracranial lesions of vascular origin. Increases in the death rate were recorded for tuberculosis, cerebrospinal (meningococcic) meningitis, diseases of the heart, pneumonia (all forms) and influenza, nephritis, suicide, homicide, motor vehicle accidents and other accidents. The death rate for cerebrospinal (meningococcic) meningitis reached epidemic proportions in 1942 in the territory, as on the mainland of the United States. Because of the increased military activity in the Hawaiian theater of operations the increase in the accident death rate was not unexpected. A large increase in deaths from air transport accidents accounted for the greater part of the increase in the accident death rate. The suicide death rate in 1942 was one of the highest recorded for the territory since its admission to the registration area. The suicide death rate increased from 14.8 per hundred thousand of population in 1941 to 22.4 in 1942. This high rate is an unusual occurrence in a war year.

GENERAL

Tropical Medicine Society Admitted to National Research Council.—At a recent meeting of the executive committee of the division of medical sciences, National Research Council, it was voted unanimously to admit the American Society of Tropical Medicine to membership in the division.

Fellowships in Child Psychiatry.—A limited number of fellowships are being offered for training in extramural child psychiatry. Selection for these fellowships is made by the National Committee for Mental Hygiene, by which eligible applicants are to be recommended for appointment, the term and plan of the fellowship to be determined by the peculiar needs of the applicant. Candidates should have at least a general internship and two years of psychiatry in an approved mental hospital in addition to other qualities fitting them for extramural service. The stipends vary slightly with location and status of the fellow but in general range between \$2,000 and \$2,400. Additional information may be obtained from Dr. Milton E. Kirkpatrick, National Committee for Mental Hygiene, 1790 Broadway, New York.

The G. I. Joe Literary Award.—E. P. Dutton and Company, Inc., New York, announces the G. I. Joe Literary Award of \$5,000 for the best book manuscript submitted by a service man or woman of any rank, in any branch of the U. S. Service, wounded in action in the present world war. Half of the cash award will be paid on acceptance of the manuscript and the other half on its publication, all as an advance against royalties, under a publisher's regular contract. Professional correspondents are excluded. In making the announcement, E. P. Dutton and Company states:

Whether these books tell the story of hope or disillusionment is not the publisher's concern. They are looking for the best selection possible of fiction or nonfiction, and poetry, which is definitely going to be written—is being written today—by the men and women who feel that they must get down in print what they think and feel about their shattered world. And it is to the wounded, first to return from the battle fronts, that the publishers offer this award.

Prize Contest for Physician Artists.—The American Physicians Art Association, through the cooperation of Mead Johnson and Company, announces a prize contest for medical officers in the armed forces and civilian physicians. "Courage and Devotion Beyond the Call of Duty" has been designated the theme of the contest, and physicians may use any one of the following mediums: painting in oil or tempera; water colors, transparent or opaque; sculpture in any medium; drawing, any medium; prints, etching, engraving, lithograph, wood block or linoleum block, and photography, including bromure, tinted and kodachrome. The purpose of the competition is to memorialize the heroism and devotion of the medical profession. The prize winning subjects will remain the property of the physician-artist, but the American Physicians Art Association shall have reproduction rights and also the privilege, for a period of three years after the close of the contest, of displaying prize winning objects at art museums, libraries, county medical societies, medical schools and similar institutions. That association shall also have the right to offer the prize winning works to any of these groups to use as murals, cornerstones, architectural designs and the like to memorialize the importance of the medical profession in war and in peace. The contest will expire May 20, 1946 in order that the prize winning objects may be ready for hanging at the annual session of the American Medical Association in June 1946. Any physician member of the American Physicians Art Association, including medical officers in the armed forces of the United States and Canada, are eligible to compete in the contest. A list of forty-two prizes will be divided equally, one set of prizes to be awarded to medical officers in the armed forces and the other to civilian physicians. Additional information may be obtained from Dr. Francis H. Redewill, secretary, American Physicians Art Association, Flood Building, San Francisco.

Suicide Rate Declines.—The suicide rate in the United States is now about one fifth lower than before the war, according to statisticians of the Metropolitan Life Insurance Company, who base their conclusions on the company's mortality records. In a release, July 27, it was stated that it is a familiar fact that suicides decline during wartime. From the two years following Pearl Harbor, 1942-1943, the suicide rate among the industrial policyholders was lower by about one fifth than the rate for the preceding three years. In 1943 the suicide death rate among these insured established a new low record. The death rate last year among this group at ages 1 to 74 was 6.8 per hundred thousand as compared with 7.7 in 1942 and 8.2 in 1941. The current records indicate that the death toll from suicide is still being further reduced. Among white male policyholders the greatest decline in sui-

cides in 1942-1943, about one third as compared with prewar years, was at the later ages, where the toll is the heaviest. Among white women the greatest percentage decline, also about one third, occurred at the younger ages, 15 to 24, where the suicide rates are at their lowest. The Metropolitan statisticians attribute the general decline in the suicide rate in recent years principally to the "prevalence of favorable economic conditions and the psychological effect of the war." It is pointed out that the sharp decrease in the number of suicides committed by men at older ages "has probably been due, for the most part, to the opportunities for employment at relatively high wages. And the economic factor has also undoubtedly played a large role in reducing suicides among adolescent girls and young women. This is particularly gratifying, since it might have been expected that the wartime conditions which have increased delinquency among young girls might also have adversely affected their suicide rate." The statisticians also express the conviction that a psychologic factor has played a part in reducing the toll from suicides "by the subordination of petty personal considerations to the broader needs of the nation at war."

Report of Academy of Pediatrics.—A far reaching program to develop medical and health services for children is reflected in the report of various committees of the American Academy of Pediatrics published in the *Journal of Pediatrics* for August. In all its activities the academy emphasizes the cooperation of its members through its state fellowship. The committee for cooperation with nonmedical groups sees a new field for cooperation with the General Federation of Women's Clubs of America, in which two million young girls are enrolled and which devotes much of its teaching and training along health lines. The committee on governmental and medical agencies, which over a period of years developed a seven point program demonstrating how a state academy fellowship could be of constructive service to better child health through cooperation with state, governmental and medical agencies, plans to present to the academy of pediatrics at its November meeting a proposed study whereby the services to these many agencies could be improved. Some of the activities needing increased integration are hospital ward service, hospital clinic service, public health conferences, preschool and child health conferences, school health services, child guidance and mental hygiene program, adolescent hygiene programs, the pediatric part of tuberculosis case finding, immunization clinics, the pediatric part of crippled children's clinics, the pediatric services involved in voluntary health insurance programs and the medical supervision of children's camps. The report of the committee on Pan American scholarships indicates that the main difficulty of persons receiving these scholarships, which were made available by several sponsoring groups, was an insufficient knowledge of English, a problem which has been recognized and since controlled. At the second Congress on Pediatrics in Mexico City, March 26-April 1, fifteen fellowships in the academy were awarded to persons residing in Mexico. The activities of the committee on national defense continue to be centered on the medical supervision of refugee children in cooperation with the United States Committee for the Care of European Children. Groups of physicians have been organized to examine and to provide medical care for these children at various reception centers before placement. Examinations have included Schick and Mantoux tests and chest x-rays of positive reactors. At intervals from April 1, 1943 to the time of the report, seven groups comprising 80 children were received in three centers located in Pleasantville, N. Y., Bronx, N. Y., and Newark, N. J. To assure the best results, the coordination and perhaps consolidation of various committees and agencies concerned with the care of children is urged. The integration of effort is particularly important both for the present emergency and for the future development of the nursery and child care centers. In the formulation of plans for particular areas the consultation of members of the academy is urged. The special committee on rheumatic fever has pledged itself to cooperate in the rheumatic fever problem and to aid in the program to be carried out by the newly organized Council on Rheumatic Fever (*THE JOURNAL*, September 2, p. 42).

CORRECTION

Hospitalization of Dependents of Naval Personnel.—In the first item appearing on page 1047 of *THE JOURNAL*, August 12, is the statement "For each patient admitted and for each day in the hospital, the member of the Navy or Marine Corps concerned shall pay \$7.75." The amount should have been \$1.75 instead of \$7.75.

Foreign Letters

LONDON

Aug. 12, 1944.

Casualties in Normandy Flown Across the English Channel

Since D day 10,000 wounded have been brought from Normandy to England in Dakota planes flown by the British Transport Command. On the outward journey the planes carry ammunition and supplies. On the return journey each plane carries 18 stretcher cases and 6 walking wounded. Because they carry supplies on the outward flight, the ambulance machines do not bear the Red Cross insignia and claim no immunity from attack, even though they are not armed. The wounded are in charge of a woman nursing orderly. Priority cases find themselves in English hospitals at home within six or seven hours of being picked up on the battle field. The nursing orderly is qualified to administer oxygen or morphine during the flight. The United States Army has a similar aerial ambulance service to the battle front. Its flying nurses are given officer status and officer pay.

Improved Vital Statistics During the War

Dr. Percy Stocks, medical statistician of the General Register Office, has described the vital statistics of 1943 (*Lancet* 2:65 [July 8] 1944). But for the influenza epidemic at the end of the year the vital statistics of England and Wales might have been as noteworthy as those of 1942. In the first three quarters of 1943 the death rate was 11.3 per thousand, compared with 11.8 and 11.7 in the corresponding periods of 1942 and the prewar year of 1938. The rates for the years 1938-1943 were 8.52, 8.49, 9.90, 9.32, 8.09 and 8.24. In 1943 new low records were established for infant mortality (49.0 per thousand live births, compared with 50.6 in 1942 and 52.8 in 1938) and for ages 1 to 5 (3.34 per thousand living compared with 3.42 in 1942 and 52.8 in 1938). The crude birth rate rose to 16.5 per thousand in 1943, giving an approximate reproduction rate of 0.903, compared with 0.810 in 1938 and 0.853 in 1942. The tuberculosis mortality, which is usually increased by war, was much the same as before the war. Comparison with 1938 shows that deaths from respiratory tuberculosis were 619 more than those in 1938 for males but 561 less for females. The cause of the improved vital statistics during the war seems to be the abolition of unemployment.

Information to Be Disclosed to Military Authorities as to the Source of Venereal Disease

A regulation of the Ministry of Health which has given rise to much criticism provides that any one reported to the health authorities by two persons for having transmitted venereal disease can be compelled to undergo examination and treatment. The ministry has now informed military authorities that information so obtained may be disclosed to medical authorities of the British, American or other allied forces so far as it is needed to secure examination and treatment of persons alleged to be sources of infection.

Forcible Vaccination of a Soldier

A labor member asked the secretary of state for war in the House of Commons whether or not the forcible vaccination of a soldier at the command of a medical officer with the aid of four men was contrary to the regulations. The secretary replied that the man in question was vaccinated in spite of his protests that he did not wish to be vaccinated. His left wrist was held by one man and his right elbow by another. The man had no conscientious objection to vaccination but refused because on a

previous occasion he suffered from a sore arm, and in his view the vaccination and inoculations he had received had done him no good. The officer concerned had clearly no right to do so, and in normal circumstances disciplinary action would be taken against him, the secretary said. But this vaccination was carried out at the Anzio bridgehead, it was pointed out; reinforcements were arriving from Naples, where there was an outbreak of virulent smallpox, and the possibility of an outbreak on the bridgehead was causing great anxiety. In these exceptional circumstances the officer's action had been considered an error of judgment committed in good faith to safeguard the health of the troops in a dangerous medical situation. The secretary therefore would not take any disciplinary action.

Radium Precautions

The Radium Committee of King Edward's Hospital Fund for London has made some important recommendations. In the future, it is recommended that the clinical supervision of radium work in hospitals should be entrusted to the Radium Commission, which already exercises this function throughout the whole of Great Britain outside the metropolitan area. Radium and irradiation work generally have too often resulted in considerable suffering. To eliminate or at least to minimize that danger it is important that such work shall be carried out only in hospitals and institutions which can provide a full team of experts—specialists, physicians, surgeons, radiotherapists and physicists. That policy should be integrated over the whole country, the committee states.

AUSTRALIA

July 3, 1944

Pharmaceutical Benefits—"Free Medicine" for Australia

As part of the social security plans of the commonwealth government, a bill to provide pharmaceutical benefits was passed by the Senate on March 2. Such benefits are defined as "(a) un compounded medicines the names of which, and medicinal compounds the formulae of which, are contained in a prescribed formulary to be known as the Commonwealth Pharmaceutical Formulary; and (b) materials and appliances (not being un compounded medicines or medicinal compounds) the names of which are contained in a prescribed addendum to the Commonwealth Pharmaceutical Formulary," these benefits, available to "every person ordinarily resident in the Commonwealth," from an approved pharmaceutical chemist or, in special circumstances, a medical practitioner "on presentation of a written and signed prescription or order (which shall be in accordance with the prescribed form and written on a form supplied by the commonwealth) of a medical practitioner."

The British Medical Association feels that its members will be hampered by being restricted to a formulary. If the prescription does not conform to the formulary the medicine will not be free. To meet this objection the government will establish a permanent committee of doctors and pharmaceutical chemists to investigate all new drugs so they may be included when necessary to keep the formulary up to date. The expense of a drug will not in itself debar the drug from being included in the formulary, provided its therapeutic efficiency is established.

The procedure will be for a patient to obtain from a doctor a prescription written on a special form, in which the doctor orders whatever medicine is necessary for treatment. This prescription will be presented to an approved chemist. The fears of the Friendly Societies that their dispensaries would be excluded from the operation of this act have been overcome by an invitation to all chemists and dispensaries to apply for approval to operate under the act.

Mr. G. G. Jewkes has been appointed director of pharmaceutical services in the Commonwealth Health Department. Mr. Jewkes was formerly chief chemist under the lapsed national health insurance scheme, and he has been attached to the Social Services Department. Mr. Jewkes's appointment will be followed soon by the formation of a pharmaceutical administrative staff in each state. These staffs will comprise a chief chemist assisted by technical officers and an organization to fix prices for prescriptions. The "free medicine" plan is expected to start early next year, as soon as preliminary administrative details have been completed. The estimated annual cost is £2,100,000.

At a Friendly Societies' conference held in Canberra it was decided that the pharmaceutical benefits taken from Friendly Societies by the commonwealth government under the free medicine plan would be replaced by other benefits. Among these would be ambulance services, home and clinical nursing and care for the aged and convalescent. State associations of Friendly Societies will press for any state legislation necessary. It was also decided to consider the possibility of a change in the present system of contract medical service to eliminate income limits. This is contrary to a long established policy of the British Medical Association, which feels, with justification, that contract medical practice should be limited to those whose income does not permit them to receive medical attention by private arrangement with their doctor.

The first reaction of the medical profession to this new pharmaceutical bill was a varying degree of opposition. The Victorian branch threatened to refuse to cooperate. Previous to the passing of the bill the Australian president of the British Medical Association (Sir Henry Newland) had met government representatives and later had issued a statement that the medical profession must be untrammelled. In January the Federal Council of the British Medical Association endorsed this view and added that all prescribed medicine should be given free. The general secretary of the Federal Council of the British Medical Association (Dr. John Hunter) spent some months in Canberra before the bill was considered, in an effort to have the act improved.

The British Medical Association is concerned about clause 15 (a) of the act. By this clause the director general of health may appoint a medical man in any area on a salary basis for the purpose of writing prescriptions so that the public may obtain free medicine. It is felt that this clause will enable the director general of health to appoint a doctor in any area where the medical men are not prepared to cooperate. Should this happen, not only would the people be able to have free medicine but they would also be able to have free prescriptions and possibly free medical attention as well. The medical profession regards this clause as a sinister step toward the introduction of a cheap form of national medical service.

Typhoid Epidemic in Victoria

In March 1943 a classic milk borne epidemic of typhoid broke out in an outer suburb of Melbourne. The report of this epidemic has now been published by the Victorian Department of Public Health. There were 440 cases, with a death rate of 5 per cent. Nearly all were primary cases. Milk was established as a vehicle of infection in a few days after the epidemic commenced. As a result of the zoning system of milk distribution the milk was distributed throughout the affected area by one dairy, the milk being sold either to the public directly or by shops or depots. Milk had been received from the dairy farms in cans, mixed and cooled in bulk and then returned to the rinsed can. The pooling of milk delayed detection of the source of infection, but the investigation ultimately resulted in the discovery of a woman carrier of typhoid. This carrier was unclean in her personal and domestic habits, and the dairy was insanitary.

The incidence of those infected was highest in the 5-14 age group, followed by the 15-24 age group. Infants under 12 months were either immune to or protected against infection. Mass inoculation against typhoid was not practiced because of want of information about its efficacy in patients already infected. Inoculation was advised in individual cases for newcomers to the district, in families with a member already a patient and for persons at continued risk, such as those attending the sick or handling infected material. One interesting point was that no soldier returned from the war of 1914-1918 developed the disease, even though there were over 200 exposed to the risk. These men have had inoculations against typhoid.

The milk which was the cause of the epidemic had not been pasteurized, and this epidemic has provided a valuable object lesson in the necessity for pasteurization. Unfortunately, even this dramatic lesson seems to have failed to impress the public and the politicians with the need for this modern essential of milk distribution. Medical men and scientists have been most outspoken in their views, but the "practical" dairyman and an apathetic public have so far won the day. However, insistence by the services for pasteurized milk is having its effect.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, July 31, 1944.

Teaching of Hygiene in Brazil

The Institute of Hygiene at São Paulo University has served as the state school of hygiene in connection with the São Paulo Medical School since 1931. It has granted several kinds of certificates recognized throughout Brazil. According to the reorganization plans for the university schools in Brazil still under consideration by the Ministry of Education, the teaching of Hygiene will be made through the School of Hygiene and Public Health organized at the universities and in the medical schools in which departments of hygiene and public health have already been developed. The reorganization of the Institute of Hygiene at São Paulo University has been approved by the University Council as well as by the National Council on Education. The teaching and future development program has been approved also by Dr. Gustavo Capanema, minister of Brazilian education, as a new and valuable element in the preparation of professional personnel and for the promotion of scientific progress.

The Rio de Janeiro Institute of Psychiatry

The Institute of Psychiatry, under the direction of Professor Henrique Roxo, is a part of the University of Rio de Janeiro, where Dr. Roxo teaches psychiatry with the assistance of Associate Professors Flavio de Souza, Rodrigo Ulysses, A. Morais Coutinho and Ibrahim Jorge and the collaboration of a few specialists in allied branches of medicine. The institute is provided with about 200 beds, which serve a large number of mental patients. As the most modern therapeutic methods (including insulin therapy, malariotherapy, metrazol shock, electric shock, occupational therapy, physical therapy, vitamin therapy and calcium therapy) are fully used at the institute, the results of treatment are considered excellent, having reached the rate of about 30 per cent cures during the last year. A main feature of the institute is that it is devoted to research as well as to teaching. Dr. Flavio de Souza has lately published several papers in which he presents the results of his studies on vitamins and mental diseases, the convulsive therapy by dicrotoxin associated with metrazol, improvements in convulsive therapy by metrazol (35 per cent dextrose solution), comparison between the clinical results of the metrazol shock and electric shock treatment and circulatory velocity and metrazol shock. Dr. Paulo Lacaz, in charge of the laboratory of

the institute, has recently published papers on the Takata-Ara reaction in neuropsychiatry, biochemical aspects of metrazol convulsions, glycid metabolism in schizophrenia, and some results in the application of interferometry. Basal metabolism in mental diseases is the special field of Dr. Ulysses, and Dr. Novais Filho deals with electroencephalographic studies in the diagnosis of psychoses.

Hospital News

The mayor of Rio de Janeiro, Dr. Henrique Dodsworth, himself a physician, has ordered that the Cascadura Maternity Hospital shall be known hereafter as the Fernando Magalhães Maternity Hospital. Dr. Magalhães was a leading obstetrician and professor at the University of Rio de Janeiro, whose death was reported in *THE JOURNAL*, April 8.

The administration of the city of São Paulo has completed the necessary arrangements to buy from the Bank of Brazil, custodian of enemy properties, the hospital now known as the Japanese Hospital of that city.

Dr. Fernando Paulino Jr., a noted young surgeon of Rio de Janeiro, recently resigned the post of director of the Miguel Pereira Hospital. This municipal hospital, with 50 beds, is a specialized institution for the surgical treatment of tuberculosis.

A fire has destroyed a section of the Municipal Hospital of the city of São Paulo. Firemen saved 40 hospital patients from injury.

Blood Typing of Brazilian Soldiers

Major Rodolfo Pereira dos Santos has cited the incidence of different blood groups among Brazilian soldiers of the Italian expeditionary forces. The blood was classified of 10,811 soldiers. Results were:

	Number	Per Cent
O type (universal donor).....	5,047	or 46.63
A type.....	4,101	or 37.94
B type.....	1,285	or 11.83
AB type (universal receiver).....	378	or 3.59
	10,811	100.00

Cesarean Section Because of Diaphragmatic Hernia

Professor Clovis Salgado of Belo Horizonte, Minas Gerais, observed a pregnant woman with diaphragmatic hernia in whom a cesarean section was performed at the onset of labor. The patient had a known tuberculous lung abscess six years previously, which emptied without operation. A left phrenectomy was performed one year later. An x-ray of the digestive tract revealed the diaphragmatic hernia showing the stomach herniated into the thorax. Tubal sterilization was performed at the time of the cesarean section.

Operability of Cancer of the Rectum

Dr. R. Pitanga Santos has a large proctologic practice in Rio de Janeiro and has investigated cancer of the rectum. At the last meeting of the National Academy of Medicine he presented several of his cancer patients. Speaking on the special topic of the operability of cancer of the rectum, Dr. Pitanga Santos pointed out his policy, followed during his long practice, of always operating in this condition, whatever the state of the patient. He declared that he has obtained good results in many cases considered hopeless by other doctors. Dr. Pitanga Santos insisted on the point that the mere age of the patient should not be considered a contraindication to surgery; he presented a woman of 84 who had been operated on at the age of 70 when she was considered by several other physicians as in a desperate plight. He presented several more aged patients who had been cured of cancer of the rectum. As a rule he employs a special surgical technic that he devised himself, using the peritoneal route, through a wide incision in three directions; this affords an ample operating field to enable the use of the electric knife, which he frequently employs.

Pathology and Clinical Treatment of the Thyroid

Under the direction of Dr. J. Peregrino Junior, the endocrinologic department of the Policlínica Geral of Rio de Janeiro, a medical institution which operates several large medical and surgical outpatient clinics, is now giving an extensive course on the pathology and clinical treatment of the thyroid. Drs. Moreira da Fonseca, Luis Feijó, Frederico MacDowell, Raymundo Brito and Xavier Pedrosa are teaching the different parts of the course. The emphasis given to the thyroid this year is explained by the increasing importance of this subject in Brazil. Of a thousand cases of glandular diseases attended at the endocrinologic department of the Policlínica, 38.7 per cent were diseases of the thyroid. In several thousand school children in the state of São Paulo Arruda Sampaio has found 18.2 per cent with goiter, and the rate reaches 60 per cent in some localities of the same state. Moreover, in spite of the fact that the thyroid is the best known of all the endocrine glands, it is in the diagnosis and treatment of its diseases that the general physician errs the most.

Brief Items

Dr. Annibal Varges, a specialist in physical medicine practicing in Rio de Janeiro since 1909, died recently at the age of 64. He was the first to suggest the simultaneous production of faradic and galvanic electric currents in the same apparatus as a therapeutic procedure.

Dr. Joaquim A. de Brito, head surgeon of the Municipal Emergency Hospital of Rio de Janeiro, and Dr. Flavio P. de Figueiredo, physician of the Division of Tuberculosis of the Department of Health of the same city, have left for the United States to spend some time, respectively, at the Massachusetts General Hospital and at the Municipal Tuberculosis Sanitarium of Chicago.

Major Arlino C. de Carvalho has been appointed ad interim director of the Brazilian Army Medical School.

Under the direction of Dr. Paulo Cesar de Andrade, the old Misericórdia Hospital of Rio de Janeiro is being progressively enlarged and refitted and the services improved. The latest addition in the plan of improvement is the publication of a medical magazine under the title *Anais da Santa Casa de Misericórdia do Rio de Janeiro*, to record the study of the cases treated in the hospital.

Dr. A. Saint-Pastous, president of the University of Porto Alegre, state of Rio Grande do Sul, recently resigned this position.

Dr. Raul Moreira, dean of the school of medicine of the University of Porto Alegre, has resigned his post. Dr. J. Pereira Filho, professor of medicine at the same school, has been appointed dean.

Col. Emmanuel Marques Porto, now stationed somewhere at the war front in Europe, has been appointed head of the Medical Service of the Brazilian Expeditionary Force. Lieut. Col. A. Marques Torres has been appointed head of the medical service of the first infantry division of the same force.

Marriages

TOM GROVER ORR JR., Kansas City, Mo., to Miss Jean De Vore Robertson of Marysville, June 24.

ROBERT MATTHEW BERNE to Miss Beth Adele Goldberg, both of New York, August 18.

DAVID OLAN MEYER to Miss Marion Louise Ingraham, both of New York, August 8.

CHARLES O. PETERS to Mrs. Mabel Rindernecht, both of Erie, Pa., April 27.

WILLIAM C. F. SMITH, Erie, Pa., to Miss Louise Falk of Warren, May 20.

Deaths

Groesbeck Francis Walsh @ Fairfield, Ala.; Northwestern University Medical School, Chicago, 1902; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Public Health Association, American Academy of Tuberculosis Physicians, National Tuberculosis Association, American Trudeau Society, American Association of Industrial Physicians and Surgeons, American Academy of Physical Medicine, American Association for the Advancement of Science, Southern Medical Association and the Alabama Academy of Science; entered the medical service of the Isthmian Canal Commission in 1905 and remained in the service until 1910; during varying periods of the time had been in charge of the line hospitals at Culebra, Las Cascades, Miraflores and La Boca; served as adviser in health matters to the republic of Nicaragua and for many months as American Consul in the Nicaraguan port of Corinto; attached to the medical department of the Madeira Mamore Railroad, engaged in constructing a line around the cataracts of the Madeira River, from 1910 to 1911; during the major portion of the time had been in charge of surgical work at Candelaria Hospital, Amazonas, North Brazil; life member of the Madeira Mamore Society, formed by the survivors of this expedition; for a year had been in charge of the medical work of the Butters Mining Company at Divisadero in the republic of Salvador; chief of the laboratory division, Naval Operating Base, Hampton Roads, Va., during World War I, and was attached to the U. S. S. *Sierra* and the U. S. S. *Montgomery*, serving six months overseas on the Naval Transport U. S. S. *Orizaba*; assistant superintendent of the health department of the Tennessee Coal, Iron and Railroad Company since 1913 and chief of the medical clinic of the Employees' Hospital since 1919; died September 1, aged 66, of carcinoma of the urinary bladder.

Jerome Kingsbury, New York; Bellevue Hospital Medical College, New York, 1897; member of the Medical Society of the State of New York, American Dermatological Association and the American Academy of Dermatology and Syphilology; specialist certified by the American Board of Dermatology and Syphilology; professor of dermatology and syphilology at the New York Polyclinic Medical School and Hospital; for five years a member of the Seventh Regiment of the New York National Guard; served in France with the American Expeditionary Forces during World War I; colonel in the medical reserve corps; surgeon of the city patrol corps; formerly on the staff of the New York Skin and Cancer Hospital; director of dermatology at the Midtown Hospital; consulting dermatologist to the Harlem Eye and Ear Hospital, New York City Hospital, Welfare Island, North Eastern Dispensary and the Northern Dispensary; attending dermatologist to the New York Polyclinic Hospital, where he died July 15, aged 73, of cerebral hemorrhage.

Edward Milum Barnes, Tampa, Fla.; Memphis (Tenn.) Hospital Medical College, 1913; on the courtesy staff of the Tampa Municipal Hospital; died July 19, aged 62, of coronary thrombosis.

Bert Montrose Barringer, Emden, Ill.; Illinois Medical College, Chicago, 1904; member of the Illinois State Medical Society; on the staffs of the St. Clara's Hospital and the Evangelical Deaconess Hospital, Lincoln, where he died July 26, aged 77, of heart disease.

Edward Theodore Biwer, Boise, Idaho; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; member of the Idaho State Medical Association; for two years a member of the health department of Chicago; for many years on the staff of St. Luke's Hospital; died July 22, aged 69.

Alexander Walter Burke, Chicago; Loyola University School of Medicine, Chicago, 1916; served in the medical corps of the U. S. Army in France during World War I; temporary medical examiner for the administrator of civil aeronautics from May 1943 to May 1944; flight surgeon at the Municipal Airport; died in a hospital at Memphis, Tenn., June 4, aged 57, of heart disease.

Joseph Butler, San Francisco; College of Physicians and Surgeons of San Francisco, 1905; died in the Southern Pacific Hospital in July, aged 71.

Edwin Myron Case @ Canton, Ohio; University of Nebraska College of Medicine, Omaha, 1933; served an internship at the St. Louis City Hospital, St. Louis; formerly a

member of the Civilian Conservation Corps in Middle River, Minn., and Crystal Springs, Ark.; on the staff of the Aultman Hospital, where he died July 22, aged 44.

James Horace Chism, Carthage, Tenn.; Vanderbilt University School of Medicine, Nashville, Tenn., 1908; died in June, aged 59.

James Brewer Cochran, Dyersburg, Tenn.; University of Tennessee College of Medicine, Memphis, 1933; member of the Tennessee State Medical Association; served an internship and residency at the Methodist Hospital in Memphis; on the staff of the Baird-Brewer Hospital, where he formerly served as medical superintendent; died July 18, aged 34, of coronary occlusion.

William Henry Copeland, La Jolla, Calif.; Bellevue Hospital Medical College, New York, 1885; died July 3, aged 84.

John Joseph Cummings @ Worcester, Mass.; Columbia University College of Physicians and Surgeons, New York, 1899; member of the New England Obstetrical and Gynecological Society; for many years on the staff of St. Vincent Hospital; died in Misquamicut, R. I., July 9, aged 74, of heart disease.

Lucius M. Ellis, Houston, Texas; Baylor University College of Medicine, Dallas, 1912; member of the State Medical Association of Texas; died July 8, aged 65.

Homer Harvey Ewing, Willard, Ohio; Cleveland Homeopathic Medical College, 1898; member of the Ohio State Medical Association; past president of the Huron County Medical Society; chairman and for many years a member of the board of health of Huron County; on the staff of the Willard Municipal Hospital, where he died July 20, aged 75, of pneumonia.

Charles William Louis Hacker @ Albany, N. Y.; Albany Medical College, 1905; served at his alma mater as clinical assistant and instructor in surgical pathology, assistant in pathology and bacteriology, lecturer, instructor in surgery, and since 1937 associate in surgical pathology; member of the American Urological Association; fellow of the American College of Surgeons; associate attending surgeon, Albany Hospital, where he died July 7, aged 60, of acute peritonitis following chronic cholecystitis.

Otto William Hinn @ Cicero, Ill.; Bennett Medical College, Chicago, 1912; on the staffs of the Loretto and Walther Memorial hospitals, Chicago; died July 20, aged 59, of heart disease.

Bertalan Hoch, Jersey City, N. J.; Magyar Királyi Erzsébet Tudományegyetem Orvostudományi, Pees, Hungary, 1923; formerly assistant in medicine at his alma mater and its hospital; served an internship at the Jersey City Hospital; died July 10, aged 46, of coronary thrombosis.

John Dan Hogue @ Altoona, Pa.; Jefferson Medical College of Philadelphia, 1905; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served overseas during World War I; member of the staff of the Mercy Hospital; examiner for the Civil Aeronautics Authority; died in the Altoona Hospital July 19, aged 62, of carcinoma of the prostate.

Thomas J. Hollingsworth @ South Haven, Kan. (licensed in Kansas in 1901); past president of the Sumner County Medical Society; died July 10, aged 89, of arteriosclerosis.

José E. Igartua @ Aguadilla, P. R.; University of Maryland School of Medicine, Baltimore, 1911; past president of the Aguadilla District Medical Association; examiner for draft board during World War I; senior medical officer, department of radiology, Aguadilla District Hospital; died May 15, aged 54, of cardiovascular renal disease.

Dominick Philip Douglas Jackson @ Little Falls, N. J.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1932; on the staffs of the St. Joseph's Hospital, Paterson, and the Community Hospital, Montclair; died suddenly July 9, aged 39, of coronary thrombosis.

Milton Carr John @ Stuttgart, Ark.; University of Nashville (Tenn.) Medical Department, 1903; served as president of the Arkansas County Medical Society; formerly counselor of the Third District of the Arkansas Medical Society; a member of the board of trustees of the Arkansas Tuberculosis Sanatorium, State Sanatorium; died June 9, aged 67.

George Brinton Kessler, Elgin, Ill.; Tennessee Medical College, Knoxville, 1899; at one time health officer of Cowley County, Kan.; a member of the Selective Service board in Sullivan during World War I; died in St. Joseph Hospital July 28, aged 79, of chronic myocarditis and arterio-sclerosis.

Frank Dietrich Kilgore, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1898; served during World War I; died June 24, aged 68.

Quintin Solomon Kocher, Bridgeville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; school physician; on the staff of the Canonsburg General Hospital, Canonsburg; died in the Mercy Hospital, Pittsburgh, June 16, aged 73, of diabetes mellitus.

Amos D. Krewson, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1889; on the staffs of the Frankford and Northeastern hospitals; died July 8, aged 82, of angina pectoris.

Ralph Curtis Lowe, Media, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1928; member of the Medical Society of the State of Pennsylvania; served an internship and residency at the Women's Homeopathic Hospital, Philadelphia; died in the Hahnemann Hospital, Philadelphia, July 2, aged 42.

August E. Lundgren, Chicago; American College of Medicine and Surgery, Chicago, 1905; for thirty-eight years an examiner for the Metropolitan Life Insurance Company; on the staff of the University Hospital, where he died July 27, aged 71, of carcinoma of prostate.

William J. Merdian, Detroit; Detroit College of Medicine, 1890; formerly health officer of Grosse Pointe Park; physician for the draft board during World War I; died June 18, aged 75.

Marie A. Olsen @ Chicago; Woman's Medical College, Chicago, 1891; an Affiliate Fellow of the American Medical Association; on the staff of the Norwegian American Hospital, where she died July 11, aged 80, of cerebral hemorrhage.

Edmund Joseph O'Shaughnessy @ New Canaan, Conn.; University and Bellevue Hospital Medical College, New York, 1899; served during World War I; major in the medical reserve corps, not on active duty; chief, emergency medical service, New Canaan defense council; on the staff of the Stamford Hospital, Stamford, where he died July 2, aged 76, of cerebral hemorrhage.

Ernest Abram Moore, Bay Minette, Ala.; Louisville (Ky.) Medical College, 1906; served during World War I; formerly mayor of Bay Minette; died June 19, aged 62, of acute dilatation of the heart and chronic myocarditis.

Ralph Marcellus Morrill, Lincoln, Neb.; Bennett Medical College, Chicago, 1900; died suddenly June 30, aged 69.

Ellwood Oliver @ Pine Plains, N. Y.; Albany Medical College, 1894; on the courtesy staff of the Vassar Brothers' Hospital, Poughkeepsie; died July 6, aged 73, of diabetes mellitus and nephritis.

James William Parker @ Chicago; University of Illinois College of Medicine, Chicago, 1920; served an internship at the Grant and Chicago Lying-In hospitals; formerly a fellow in surgery at the Mayo Foundation in Rochester, Minn.; served during World War I; on the staff of the Chicago Memorial Hospital; died in the Illinois Central Hospital July 16, aged 49, of chronic intestinal obstruction.

George Alpha Potter, Danville, Ill.; Barnes Medical College, St. Louis, 1903; member of the Illinois State Medical Society; on the associate staff of the Lake View Hospital, where he died July 9, aged 68, of carcinoma of the prostate.

Jesse David Price, Michigan City, Ind.; Louisville (Ky.) Medical College, 1906; member of the Indiana State Medical Association; on the staff of St. Anthony Hospital, where he died July 3, aged 72, of cerebral hemorrhage.

Otis L. Ray @ Raleigh, N. C.; University College of Medicine, Richmond, 1899; for many years a member and chairman of the county board of commissioners; on the staff of the Rex Hospital, where he died July 4, aged 65.

Wilbur Fisk Reed, Cheboygan, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1877; member of the Michigan State Medical Society; for many years city health officer and county coroner; at one

time physician at the State House of Correction and Reformatory, Ionia; died June 30, aged 93, of senility.

Fred Hooper Rhoades @ Hanover, Kan.; University Medical College of Kansas City, Mo., 1905; past president and secretary of the Washington County Medical Society; at one time secretary of the board of health in Altoona; clerk of the local school board for twenty-one years; health officer of Washington County; surgeon for the Union Pacific Railroad for many years; died in the Lutheran Hospital, Beatrice, Neb., June 19, aged 64.

Como Perry Richards, Everett, Wash.; University of Oregon Medical School, Portland, 1893; died May 20, aged 84, of uremia.

W. Herbert Scholtz, La Crescenta, Calif.; California Medical College, San Francisco, 1889; College of Physicians and Surgeons of San Francisco, 1901; died in Los Angeles June 9, aged 80.

Edgar Lane Tiner, Crystal City, Texas; University of Texas School of Medicine, Galveston, 1929; member of the State Medical Association of Texas; served an internship at the Santa Rosa Infirmary, San Antonio; city and county health officer; died in the Crystal Hospital June 22, aged 40, of chronic myocarditis and uremia.

Thomas Henry Trainor @ Maple Park, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; died July 5, aged 81, of heart disease.

Herbert Dillon Walker @ Elizabeth City, N. C.; University of Maryland School of Medicine, Baltimore, 1902; past president of the Seaboard Medical Society; honorary member and past vice president and treasurer of the Medical Society of the State of North Carolina; for many years associated with the U. S. Public Health Service; on the staff of the Albemarle Hospital; died in the Norfolk General Hospital, Norfolk, Va., July 7, aged 67, of cerebral hemorrhage.

Charles M. Walrath, Ellicottville, N. Y.; University of Buffalo School of Medicine, 1885; formerly a druggist; served as attending physician to the Erie County Penitentiary; formerly a trustee of the village, where he served as mayor, postmaster, health officer and member of the school board; died July 9, aged 83, of chronic myocarditis and arteriosclerosis.

John William Weber, Beverly Hills, Calif.; Columbia University College of Physicians and Surgeons, New York, 1918; at one time on the staffs of the New York State Hospital in Ray Brook and the Santa Clara County Hospital in San Jose; formerly medical director of the Alhambra

Tri-County Tuberculosis Sanatorium in Alhambra; partner and medical director of aircraft workers medical plan at the Douglas Aircraft Company, Santa Monica; died in Long Beach July 4, aged 51, of coronary occlusion.

Arthur Ellwood Whittaker @ Zelienople, Pa.; University of Pittsburgh School of Medicine, 1912; served in the medical corps of the U. S. Army during World War I; on the staffs of the Rochester General Hospital, Rochester, and the Ellwood City Hospital, Ellwood City; author of "History of Ellwood City"; died July 4, aged 56, of coronary occlusion.

Joseph Carlin Williamson @ Columbus, Ohio; Medical College of Ohio, Cincinnati, 1899; died July 5, aged 69.

KILLED IN ACTION

John Hall Bates, New Preston, Conn.; Yale University School of Medicine, New Haven, 1941; served an internship at the Royal Victoria Hospital, Montreal, Que., Canada; commissioned a lieutenant (jg), medical corps, U. S. Naval Reserve, on April 20, 1942; began active duty on July 15, 1942; aged 31; killed in action in the Pacific area; presumptive date of death February 2, according to the Navy Department.

LIEUT. (JG) JOHN H. BATES (MC),
U.S.N.R., 1912-1944

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices or cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

Aseptex.—In December 1943 Solinger & Sons Company, Inc., New York, stipulated with the Federal Trade Commission that it would cease representing that certain mattress ticking which it treats with this product possesses such bactericidal, germicidal or fungicidal properties as to make the fabrics resistant to germs, bacteria, fungi or vermin. The respondent also agreed to cease using the words "Sanitary" and "Aseptex" to describe such ticking, so as to imply that the fabrics will be effective in preventing, checking or removing agencies, such as filth and infection, which are injurious to health.

Formula SBS-11.—The Sugar Beet Products Company of Saginaw, Mich., which puts this out, entered into a stipulation with the Federal Trade Commission in January 1944, agreeing to discontinue certain misrepresentations in its advertising. Among these were that its product is effective in the prevention or treatment of skin irritations, dermatitis, chapping or soreness; that it will remove all bacteria from the skin or can be depended on to prevent infections or act as an antiseptic under the conditions of use, or that all commercial liquid soaps contain alcohol. The concern further agreed to cease representing that Formula SBS-11 will "remove 21.3% more bacteria than any other products available" or making any other claim attributing to the product an effectiveness, either in the removal of bacteria from the surface of the skin or in the prevention of skin infections, which is exaggerated or for which there is no proper support based upon any recognized or accepted scientific test.

Kulver's East Indian Hair Dressing.—In February 1944 Wilfred Scott, trading as Decco Barber Supply Company, Roxbury, Mass., stipulated with the Federal Trade Commission that he would cease representing that this product is a hair grower, produces long hair or in any way facilitates the growth of hair, and designating such preparation as "East Indian Hair Dressing" or otherwise representing that it is a product of, or contains ingredients imported from East India or any other foreign country.

Lee's Periodic Pills and Lee's Periodic Capsules.—In December 1943 one Milton L. Lieberman, trading as Lee Products and as Chemi-Culture Laboratories, Chicago, stipulated with the Federal Trade Commission that he would cease using the word "Periodic" or other similar connotation as a part of the trade designation of these products, or referring to the menstrual period in any way which might indicate that such preparations have predictable or reliable influence on that period. Further, he agreed to cease representing that either of the preparations is based on a well known formula that has been used successfully for such purpose; to cease using such designations as "XXX" or "triple strength" as indicative of the extra strength or unusual potency of such preparations, or employing the word "Laboratories" as a part of his trade name, until such time as he may actually own or operate a laboratory for his business. Lee also stipulated that in regard to any of his preparations containing a laxative, he would discontinue any advertisement which did not clearly reveal the potential danger in using such products in the presence of symptoms of appendicitis; as to any of his preparations containing opium or pennyroyal, he agreed to discontinue any advertisements which did not disclose that the use of such products may produce irritation of the kidneys. It was provided, however, that if directions for use of each of such preparations, whether on the label or in the labeling, should contain specific and adequate warnings of its potential danger to health, such advertisements need bear only the warning, "Caution: Use Only as Directed."

Orjene Pure Shampoo, Vi-Vu Scalp Treatment, V-Kol and Couleur de Ton.—These are put out by the Orjene Company of New York. In a stipulation that it entered into with the Federal Trade Commission in November 1943, it agreed to cease representing that the shampoo is a cure or remedy for dandruff or is of any help in that condition beyond the removal of dandruff scales; that Vi-Vu will promote or restore a healthy growth of hair, remove local scalp irritations or renew life-giving nutrient; that V-Kol is a cure for itching scalp or skin, eczema or dandruff, or will aid nature in growing healthy hair. The respondent further agreed to discontinue any advertisement of Couleur de Ton which did not conspicuously reveal that the product contains ingredients which may cause skin irritation in certain individuals, and that the preliminary test outlined in the directions should first be made; that the product should not be used for dyeing the eyelashes or eyebrows, lest it cause blindness; provided, however, that it would be sufficient to advertise, "Caution: Use Only as Directed on Label" if such label should bear first-mentioned caution conspicuously and the accompanying labeling should give adequate directions for such preliminary testing before each application.

Presto Face Cream.—This is put out by T. L. Miller, trading as the T. L. Miller Manufacturing Company, New Orleans. In December 1943 he entered into a stipulation with the Federal Trade Commission, agreeing to cease representing that the use of this cosmetic will produce a clear, smooth skin or, by use of the word "Manufacturing" or similar words in its trade name or otherwise, that he owns or operates a company engaged in the business of manufacturing or compounding the preparation. Further, he agreed to discontinue any advertisement which represented that Presto Face Cream is safe to use, or failed to reveal that it should not be applied to an area of the skin larger than the face and neck at any one time; that too frequent applications or use over excessive periods of time should be avoided; that adequate rest periods between series of treatments should be observed; that the product should not be applied to areas where the skin is cut or broken, and that prior to its use a proper patch test should be made to determine whether the user is allergic or sensitive to the cream. It was provided, however, that such advertisements need only contain the statement: "Caution: Use Only as Directed" if the directions in the labeling carry a warning to the same effect.

Ultraviolet Ray Lamps.—In November 1943 Science Laboratories, Inc., and Sperti Electric Company, Inc., Cincinnati, entered into a stipulation with the Federal Trade Commission, agreeing to discontinue the following advertising misrepresentations for their models IC-77 and HI-41 lamps, or any of similar construction: That conditions of the modern age are such that the public is deprived of most of the benefits of sunlight or (by inference) that health depends on obtaining such radiation by artificial means; that the low death rate in summer as compared with the high death rate in winter is an index to the deficiency of ultraviolet light in winter; that the lamps offered for sale without adequate filter equipment produce ultraviolet rays, or that such radiation is comparable to sunshine. Further, they agreed to discontinue the misrepresentations that these lamps are indispensable for expectant or nursing mothers; that the lamps are an aid to skin health, or to a clear, unblemished complexion in general, or that their irradiation relieves all types of pains and aches or is an effective treatment or remedy for every variety of soreness and congestion.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Gloria Laxative Pills, or Rx S368230 Pills.—Parke, Davis & Company, Detroit, manufacturer, and John A. Smith Company, Oconomowoc, Wis., distributor. Various shipments between Jan. 13, 1941, and July 14, 1942. Composition: aloin and an extract of cascara sagrada. Misbranded because labeling failed to give any directions for use or to warn that pills were not to be taken in the presence of abdominal pain, nausea, vomiting or other symptoms of appendicitis, and that frequent or continued use might result in dependence on laxatives. Further misbranded because label failed to give common or usual name of active ingredients, since "Cascara Bitter" is not the common or usual name of any substance.—[D.D.N.J., F.D.C. 761, September 1943.]

My-X-Ym.—My-X-Ym Food Enzymes Products, Chicago. Shipped March 2, 1942. Composition: essentially ground senna pods, powdered milk, yeast, wheat bran, cornstarch, cacao powder, soybean tissues and sugars including dextrose and sucrose. Misbranded because labeling failed to warn adequately that, as a laxative, the product should not be taken in cases of nausea, vomiting, abdominal pain or other symptoms of appendicitis, or that frequent or continued use of a laxative might establish a habit; also misbranded because label falsely represented and suggested that My-X-Ym was an enzyme product and, when used as directed, would balance the weight of the body, be efficacious "for health" and supply a factor whose absence would result in many ailments; would cause the glandular system to function properly and would restore energy and vigor; would detoxify the system and prove an adequate treatment for a long catalog of disorders, including allergic eczema, pancreatic indigestion, acidosis, colitis, gallbladder trouble, neuritis, obesity and hemorrhoids, and prevent catarrhal conditions in many parts of the body.—[D.D.N.J., F.D.C. 765, September 1943.]

Vita-Port Vitamin B₁ Tonic.—Seized in May 1942 when offered for sale by Super Cut Rate Drugs, Washington, D. C. Composition (claimed): "Each fluid ounce contains thiamin hydrochloride (Vitamin B₁) . . . 4 mg. (Equivalent to 1330 International units) Alcohol 20 Per cent. . . . Misbranded because label statements, "Here's Health! . . . Recommended for Underweight—Loss of Appetite Nervousness" were false and misleading, since the product would not be an effective treatment for such conditions.—[D.D.N.J., F.D.C. 787, September 1943.] Also declared misbranded under the provisions of the law applicable to foods, as reported in F.N.J. 3841.

Correspondence

RESEARCH IN THE SAN DIEGO ZOO

To the Editor:—In THE JOURNAL, July 8, page 729, is an item on the research center planned by the New York Zoo with the mention that the plan is "unique, . . . the first time any zoo has tried to collaborate with science." For the record would you please at some time note that there has been such a research hospital here for many years and that the New York authorities have been in communication with Mrs. Belle Benchley, in charge of the San Diego Zoo ("Life in a Man Made Jungle," "My Friends, the Apes") regarding the layout here.

We believe that this San Diego research institute has been unique. For many years any science worker whose project was approved by the committee could be assigned free laboratory space and the use of considerable equipment while his work progressed toward completion and publication, with whatever help he might ask from a committee of widely varied interests. For several years up until the war there were two research students who received a yearly fund for work applicable to zoo problems. Among workers who have published articles from this research institute are Dr. Jackson Kiser, Dr. Lawrence Penner, Dr. Robert Udall, Dr. Charles Schroeder, Dr. Leo Conti, Dr. George Kilgore, Dr. M. Wiener, Dr. F. D. McKinney, Dr. Jacob Traum, Dr. Joshua Bailey, Mr. Willys Doetschman and one of the founders, Dr. Harry Wegeforth. A note in THE JOURNAL might be of interest to medical men who wish to do research and would be glad to avail themselves of our facilities.

RAWSON J. PICKARD, M.D., San Diego.

Chairman, Biological Research Institute of the Zoological Society of San Diego, Balboa Park.

TREATMENT OF HEMANGIOMAS

To the Editor:—In THE JOURNAL, August 5, Dr. Merlin T. R. Maynard discussed my communication (May 27, p. 302) in which I commented on the article by Dr. George V. Kulchar on the treatment of hemangiomas in his article on "Benign and Malignant Tumors of the Foot" (March 18, p. 761).

Dr. Maynard insists that all angiomas sensitive to radiation should be treated from the day they are discovered if they show any tendency to grow. I want to reassert that simple strawberry and cavernous angiomas, contrary to general dermatologic opinion, do not require any treatment for the reason I previously stated (May 27, p. 302). This will be the subject of an article to appear in the *Journal of Pediatrics*. I should like to call the attention of pediatricians and all other physicians who care for children to the article by W. A. Lister (The Natural History of Strawberry Naevi, *Lancet* 1:1429 [June 25] 1938) in which he relates that 93 strawberry and cavernous angiomas followed for a period of from one to seven years spontaneously involuted by the fifth year of life.

Dr. Maynard relates the case of a vascular lesion on the head of an infant, enlarging to the size of a grapefruit at the end of a year and requiring surgery because of hypertrophy of the heart. I cannot conceive, from a physiologic point of view, how a simple strawberry or cavernous angioma could produce a cardiac hypertrophy. If the vascular lesion actually was responsible for the cardiac hypertrophy, an arteriovenous aneurysm or communication must have been present and a bruit should have been detected on auscultation of the lesion.

C. RUSSELL ANDERSON, M.D., Los Angeles.

CANCER NOT ASCRIBED TO SINGLE INJURY

To the Editor:—There have been two recent editorials on Workmen's Compensation for Cancer Ascribed to Single Injury. The following quotation from C. A. Joll in *Selected Papers for the Royal Cancer Hospital (Free)*, vol. 2, 1939-1940 is pertinent:

"Reliable evidence that a single trauma can produce in its train, early or late, a malignant tumor is entirely lacking, both experimentally and clinically. In my own twenty-five years' experience at the Royal Cancer Hospital and elsewhere, I have never seen a case of 'traumatic' cancer which on critical examination could be substantiated."

ISABELLA H. PERRY, M.D.,
Division of Pathology,
University of California Medical School,
San Francisco.

"FIRST INSTITUTION FOR EPILEPTIC"

To the Editor:—In the July 29 issue of THE JOURNAL at the foot of page 897 is an item entitled "First Institution for the Epileptic." Unless one was well acquainted with the institutional treatment of epileptic patients one might be misled by this article. In the first place "the first institution specifically for epileptics was established in Gallipolis, Ohio, in 1890 and opened in 1893." This statement is true as far as the United States is concerned. Much older institutions were established for the epileptic at Ghent, Belgium, and at Bielefeld, Germany, where I visited the Bethel colony in 1908. One of the earlier institutions established in our country was the State Hospital for Epileptics at Parsons, Kan., in 1903. I happen to be quite well acquainted with this institution in that I was assistant physician and assistant superintendent there from January 1904 for almost three years. The Kansas institution was the fourth institution established for the treatment of the epileptic in the United States, if my memory serves me correctly. This institution admits and treats sane and insane epileptic patients.

A. L. SKOOG, M.D., Kansas City, Mo.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES
Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Sept. 9, page 126.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Nov. 13-15. Part III. Various centers, September or October. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: Written. Part I. Various centers, Jan. 19. Final date for filing application is Oct. 21. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF INTERNAL MEDICINE: February. Final date for filing application is Dec. 15. Asst. Sec., Dr. W. A. Werrell, 131 University Ave., Madison 5, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written. Part I. Various centers, Feb. 3. Sec., Dr. Paul Titus, 1015 Highland Blvd., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, January. Final date for filing application is Oct. 1. New York, June. Chicago, Oct. 1945. Final date for filing application is Dec. 1. Sec., Dr. S. Judd Beach, 56 Ivie Road, Cape Cottage, Maine.

AMERICAN BOARD OF OTOLARYNGOLOGY: Oral. Chicago, Oct. 47. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City, Ia.

AMERICAN BOARD OF RADIOLOGY: Oral. New York, April 1945. Final date for filing application is Dec. 1. Sec., Dr. C. A. Altmach, 1137 First Ave., New York 17.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY: Oral. New York, December. Final date for filing application is Sept. 30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N.W., Washington 1, D. C.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Workman's Right to Procure Physician at Employer's Expense on Employer's Failure to Furnish Physician.—In the course of his employment, in May 1942 Caldwell sustained a low back sprain. Because he commuted from his home in New York City to his employer's plant in Bridgeport, Conn., the employer's first aid department instructed him to consult his family physician in New York City for necessary medical aid. The employer later paid compensation to the workman through Aug. 13, 1942, including the fees of Dr. Cohen, Caldwell's family physician. About the latter date the workman was sent to Bridgeport by his physician for further treatment by the employer's physician and was in turn discharged by him August 15 and sent home. Two weeks later the workman was unable to return to work in Bridgeport "because of pain and disability," and on August 18 he resumed treatments with Cohen. Cohen notified the employer of the facts and requested authority to treat the patient, but the employer made no reply until September 23, when a letter was received by Cohen stating that the workman had not yet been discharged by the employer's physician and that the employer disclaimed liability for Cohen's bill. Cohen nevertheless continued to render necessary care for the workman and eventually submitted a bill for \$163, which admittedly was reasonable. Later the workman instituted proceedings for compensation under the workmen's compensation act of Connecticut and was awarded compensation, including the amount of Cohen's bill, by the commissioner who heard the matter. The employer appealed to the superior court of Fairfield County, Conn., which remanded the case back to the commissioner for a finding as to whether or not there was expressed or implied authority given by the employer for the treatments or whether or not in view of the previous conduct of the parties the employer was estopped from denying that he had authorized Cohen to render the necessary treatment to the workman. The commissioner found an estoppel and the employer again appealed to the superior court, which vacated the award of compensation to the extent of Cohen's bill. The workman then appealed to the Supreme Court of Errors of Connecticut.

On the second appeal the trial court considered only the narrow question of estoppel. Much broader considerations, said the Supreme Court of Errors, were involved. The applicable part of the workmen's compensation act (General Statutes Act 5232) provides as follows:

The employer, as soon as he shall have knowledge of any such injury, shall provide a competent physician or surgeon to attend the injured employee, and in addition shall furnish such medical and surgical aid or hospital service as such physician or surgeon shall deem reasonable or necessary. In the event of the failure of the employer promptly to provide such . . . service, the injured employee may provide such . . . service at the expense of the employer

This was the basis of the original award. That award still stands, the commissioner merely adding certain further findings when the matter was referred back to him by the trial court. When the employee was unable to go to his work at Bridgeport and went back to his New York physician, that physician reported the need of treatment, yet the employer did nothing from August 18 to September 23. Under these circumstances the commissioner could properly consider that under the statute the employee was entitled to get treatment from his own doctor at the employer's expense. The liberality with which we treat the employee's rights under the statute, said the court, is apparent in *Bongialatte v. H. Wales Lums Co.*, 97 Conn. 548, 550, 117 A. 696, 697. In that case the medical bills were incurred before the employer had notice of the injury. Nevertheless the court said

If, in the absence of an immediate notice to the employer of the injury, he fails to provide medical aid, through ignorance of the injury or otherwise, and the employee employs medical aid, the employer is required to reimburse the employee for such expenditure if the same is reasonable as to amount and if the competency of the aid so employed is also reasonable so that the employer is not prejudiced thereby.

In the instant case, immediate notice was given, and the competency of the physician is not in question. See also *Thompson v. Towle*, 98 Conn. 738, 740, 120 A. 503; *Henderson v. Mazzotta*, 113 Conn. 747, 753, 157 A. 67. The underlying reason for the statute, sec. 5232, is stated in *Carney v. Plimpton Mfg. Co.*, 111 Conn. 401, 405, 150 A. 305, 307: it recognizes "the legislative idea that the employer as well as society benefit by the early restoration to health of the injured employee." The employer's appeal should have been dismissed.

Accordingly, the Supreme Court of Errors ordered, in effect, that the trial court dismiss the employer's appeal from the commissioner's award of compensation, which award included the physician's bill.—*Caldwell v. United States Aluminum Co.*, 38 A. (2d) 6 (Conn., 1944).

COMING MEETINGS

- American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 8-12. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.
- American Academy of Pediatrics, St. Louis, Nov. 9-11. Dr. Clifford G. Grulec, 636 Church St., Evanston, Ill., Secretary.
- American Hospital Association, Cleveland, Oct. 2-6. Mr. George P. Bugbee, 18 East Division St., Chicago, Executive Secretary.
- American Pediatric Society, Atlantic City, N. J., Sept. 25-27. Dr. Hugh McCulloch, 325 N. Euclid Ave., St. Louis 8, Secretary.
- American Public Health Association, New York, Oct. 3-5. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.
- American Roentgen Ray Society, Chicago, Sept. 24-29. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.
- Association of American Medical Colleges, Detroit, Oct. 23-25. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.
- Association of Military Surgeons of the United States, New York, Nov. 2-4. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.
- Colorado State Medical Society, Denver, Sept. 27-29. Dr. John S. Bouslog, 337 Republic Bldg., Denver 2, Secretary.
- District of Columbia, Medical Society of the, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.
- Indiana State Medical Association, Indianapolis, Oct. 3-5. Mr. T. A. Hendricks, 23 East Ohio St., Indianapolis 4, Executive Secretary.
- Inter-State Postgraduate Medical Association of North America, Chicago, Oct. 17-20. Dr. Arthur G. Sullivan, 16 N. Carroll St., Madison, Wis., Managing Director.
- International College of Surgeons, U. S. Chapter, Philadelphia, Oct. 3-5. Dr. Desiderio Roman, 250 South 17th St., Philadelphia, Secretary.
- Kansas City Southwest Clinical Society, Kansas City, Mo., Oct. 2-4. Dr. William M. Korth, 1115 Grand Ave., Kansas City 6, Mo., Secretary.
- Kentucky State Medical Association, Lexington, September 18-20. Dr. P. E. Blackerby, 620 S. Third St., Louisville, Secretary.
- Michigan State Medical Society, Grand Rapids, Sept. 27-29. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.
- Midwestern Section of American Federation for Clinical Research, Chicago, Nov. 2. Dr. Richard H. Lyons, University Hospital, Ann Arbor, Mich., Secretary.
- Mississippi Valley Medical Society, Peoria, Ill., Sept. 27-28. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.
- Oklahoma City Clinical Society, Oklahoma City, Oct. 23-26. Dr. L. C. McHenry, 512 Medical Arts Bldg., Oklahoma City, Secretary.
- Omaha Mid West Clinical Society, Omaha, Nebraska, Oct. 23-27. Dr. J. D. McCarthy, 1036 Medical Arts Bldg., Omaha 2, Secretary.
- Pennsylvania, Medical Society of the State of, Pittsburgh, Sept. 19-21. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.
- Radiological Society of North America, Chicago, Sept. 24-29. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.
- Virginia, Medical Society of, Richmond, Oct. 23-25. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.
- Wisconsin, State Medical Society of, Milwaukee, Sept. 18-20. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

14:253-306 (May) 1944

- Myasthenia Gravis: Report of 2 Cases with Necropsy Findings. A. S. Giordano and J. L. Haymond.—p. 253.
 *Pathologic Findings in Nerve and Muscle in Poliomyelitis. W. B. Dublin, B. A. Bede and B. A. Brown.—p. 266.
 Phenol Studies: VII. Chronic Phenol Poisoning, with Special Reference to Effects on Experimental Animal of Inhalation of Phenol Vapor. W. B. Deichmann, K. V. Kitzmiller and S. Witherup.—p. 273.
 Influence of Purified Diets on Toxicity of Promin. G. M. Higgins.—p. 278.
 Jaundice in Amyloidosis of Liver. D. M. Spain and R. L. Riley.—p. 283.
 Postmortem Studies in Mental Patients: Frequent Findings in Paranoid States. O. J. Pollak.—p. 289.
 Carcinoid Tumors of Ileum (Argentaffinomas). C. E. McLeod.—p. 301.

Nerves and Muscles in Poliomyelitis.—Dublin and his co-workers studied biopsy specimens of muscle from 3 patients with poliomyelitis with the method of Ranvier. A boy aged 6 years, who was considered to have anterior poliomyelitis of nonparalytic type and to show "spasm" and "alienation," was studied by biopsy thirty-five days after the onset of symptoms. A youth aged 18 years with a moderate degree of paralytic weakness was studied by biopsy forty days after the onset of symptoms. A girl aged 12 years with severe flaccid paralysis was studied by biopsy forty-eight days after the onset of symptoms. Degeneration of nerve fibers, motor end plates and muscle fibers was seen in degree commensurate with the degree of paralysis. The irregularity of distribution was in keeping with the irregularity of distribution of injury to nerve cells of the gray matter of the spinal cord. Degeneration of nerve fibers consisted largely of failure to stain axons together with preservation of cellular elements of capsules of motor endings and of sheaths of Schwann. Atrophy of muscle fibers appeared in the form of pyknosis introduced by loss of cross striations and increase of longitudinal markings. Degeneration of nerve and muscle probably was secondary to injury to nerve cells of the spinal cord.

American J. Digestive Diseases, Fort Wayne, Ind.

11:173-204 (June) 1944

- *Inhibition of Peptic Activity in Treatment of Peptic Ulcer. F. Steigmann and A. R. Marks.—p. 173.
 Vitamins and Hormones in Nutrition. B. F. Sieve.—p. 179.
 Changes in Sensitivity to Allergenic Foods in Arthritis. J. A. Turnbull.—p. 182.
 Role of Fat Soluble Vitamins A and D in Nutrition. J. Buckstein.—p. 190.
 Hypoglycemic Reaction with Convulsions in Ascariasis (Case Report). L. L. Frank.—p. 195.
 Regional Enteritis. J. R. Phillips.—p. 197.

Inhibition of Peptic Activity in Peptic Ulcer.—Steigmann and Marks carried out the following procedures on patients admitted to Cook County Hospital with diagnosis of peptic ulcers: A Rehfuss tube was introduced into the stomach of the fasting patient, and an attempt was made to aspirate the entire gastric contents. With the tube in situ the patient ate four Unceda crackers and drank one glass (200 cc.) of water. Samples of gastric juice were aspirated every fifteen minutes for two hours. The pH and peptic activity were determined in each of the specimens. On succeeding days the same procedure was repeated but the patient received, shortly after taking the crackers and water, either (a) one capsule (100 mg.) of sodium lauryl sulfate, (b) two capsules of sodium lauryl sulfate, (c) 2 Gm. of calcium carbonate, (d) 8 cc. of an aluminum hydroxide preparation or (e) two tablets of a magnesium hydroxide compound. Each patient was tested on five successive days. A

similar group of patients were given the usual ulcer diet plus one capsule of sodium lauryl sulfate every hour for twelve hours or more, depending on the patient's symptoms. These patients were observed during their stay in the hospital and later as outpatients. The authors found that calcium carbonate and aluminum hydroxide preparations, magnesium hydroxide and sodium lauryl sulfate caused decreased peptic activity simultaneously with a rise in the pH. Calcium carbonate, the aluminum hydroxide preparation and magnesium hydroxide caused more pronounced peptic inhibition than sodium lauryl sulfate. The authors were unable to confirm the reported observation that sodium lauryl sulfate inhibits peptic activity in the presence of an unaltered pH. Clinical use of sodium lauryl sulfate in a small number of patients on the usual dietary peptic ulcer management failed to reveal any superiority of this medication over some of the other medications used.

 Prophylactic Value of Sulfathiazole Against Neonatal Gonococcal Conjunctivitis. M. Gleich, M. L. Blumberg and A. S. Mason Jr.—p. 472.
 Comparison of Westergren and Kato Erythrocyte Sedimentation Rate Readings: Relation to Clinical Status of Children with Rheumatic Fever. J. B. McKinley and R. L. Jackson.—p. 474.

Erythroblastosis Fetalis: Clarification of Term.—Macklin defines erythroblastosis as a condition in which the blood of the fetus exhibits immature cells of the erythrocytic series which are not normal, either as to type or as to quantity, for the stage of development of the fetus. This condition may be elicited by numerous factors, may or may not be accompanied with hemolysis and may or may not be accompanied with extramedullary hemopoiesis. It includes hemolytic disease of the newborn as well as erythroblastosis due to factors other than hemolysis. When it is due to an antigen-antibody reaction there will be hemolysis with accumulation of iron in the fetal liver, and there will usually be persistent extramedullary hemopoiesis. This form of erythroblastosis is hemolytic disease of the newborn. In the majority of instances the hemolysis appears to be due to the Rh factor complex. Factors such as anoxemia cause erythroblastosis, as here defined, but not hemolysis. If they begin to operate early in development, extramedullary hemopoiesis will persist; if they begin just before term, formation of blood may be restricted to the bone marrow. A tentative explanation of the failure to find antibodies in the blood of the mothers of some fetuses showing erythroblastosis is advanced. It is based on a supposed immaturity of the antigen as it exists in the immature red cell, with a corresponding specificity of the antibody for this particular antigen. At present the demonstration of the antibody depends on its reaction with the antigen as it exists in the mature red cell. Testing of the blood of the mother with that of the fetus may demonstrate the presence of such antibodies. Another possible explanation is based on the recently discovered fact that there are at least six different Rh factors. Preparations of only the two commoner types of antigen are employed in the usual tests.

Atelectasis Complicating Acute Poliomyelitis.—According to Cooperstock a number of factors predispose to the development of atelectasis in paralysis of the respiratory muscles due to poliomyelitis. Foremost among them is the reduction of vital capacity. Also important is the fact that the ability to cough is impaired in poliomyelitis. Failure to rid the bronchial airways of exudate leads to bronchial occlusion and atelectasis. Should the obstructing material contain infective agents, as it invariably does, the situation is then fertile for the development of secondary pneumonia. It is thus apparent that in poliomyelitis with paralysis of the respiratory muscles there exists a constant threat of the development of grave pulmonary complications. For a patient already encumbered with serious fluidity,

the advent of such complications may well spell disaster. It is therefore of interest to record 4 instances, in 3 of which unexpected recovery took place. In all 4 atelectasis developed after the acute phase of the disease had passed, the pulmonary complications occurring from three weeks to one year after the admission of the patient to the hospital. Three of the patients were still in the respirator, and for the fourth patient the use of the respirator had been discontinued only four days prior to the occurrence of atelectasis. The patients had extensive paralysis of all extremities in addition to involvement of the muscles of respiration. The favorable outcome in the 3 patients who recovered followed the occurrence of a critical clinical picture due to the development of secondary pneumonia. Recovery appeared to depend on the favorable effect of sulfonamide compounds on the pneumonic process, permitting ultimate spontaneous clearing of the atelectasis. In the prophylaxis against pulmonary complications, avoidance of exposure to infections of the respiratory tract is of utmost importance. With the occurrence of such infections the early institution of chemotherapy may be effective in preventing the development of more serious complications. The continued use of the mechanical respirator under such circumstances is essential. Although not employed in the cases reported here, the early use of bronchoscopy for the relief of bronchial occlusion may minimize pulmonary complications under such circumstances. It is of interest that in patients already so seriously handicapped by poliomyelitis spontaneous clearing of atelectasis is possible.

Tick Borne Encephalitis.—Smorodintsev reviews the work done in Russia on isolation of the virus causing tick borne or spring-summer encephalitis. The disease is characterized by an incubation period of eight to eighteen days, a temperature rise to 100.4 to 104 F., violent headache, pain in the nape of the neck, vertigo and vomiting. The predominant physical signs are meningismus and focal lesions of the central nervous system rapidly followed by paralysis of the limbs, neck and back. In some cases an ascending paralysis involves the cervical segments of the spinal cord, reaching the medulla, to develop bulbar palsy associated with dyspnea, cardiac arrhythmia, dysphagia and aphonia. The mortality rate ranges from 20 to 30 per cent. Death usually occurs between the third and the eighth day. Many convalescents are physically disabled by paralysis and atrophy of the cervical muscles and shoulder girdle. The patients who recover do not display Parkinson's syndrome occurring in von Economo's lethargic encephalitis. Spring-summer encephalitis in the European part of Russia takes a milder course, with a mortality rate of only 10 per cent. The histopathology of spring-summer encephalitis is characterized by intense inflammatory and degenerative changes of the nervous systems. The pia mater of both brain and spinal cord is always involved. The disease may be classified as an acute nonsuppurative meningoencephalopolyomyelitis. An acute serous exudate appears on the meninges, and the brain is softened and congested, while numerous hemorrhages appear on the brain stem, the medulla, and in the horns of the spinal cord. The causative agent is a virus which passes through the finest Berkefeld and Chamberland filters. It belongs to type B of seasonal encephalitis. The virus cannot be neutralized by the serums of patients recovered from the lethargic Economo encephalitis. It also differs from the St. Louis virus in its antigenic and immunogenic properties. According to recent observations by

Casals, spring-summer encephalitis virus bears a close relationship to louping ill virus through complement fixation, neutralization and intraperitoneal cross resistance tests. Intracerebral cross resistance tests, on the other hand, were negative. Neither spring-summer encephalitis nor louping ill virus appeared to be related to the viruses of Japanese, St. Louis and West Nile types of encephalitis. Tick borne encephalitis is distinctly seasonal. It begins at the end of April and assumes epidemic proportions in May. Prior to May and after August there occur only sporadic cases. Moderate atmospheric temperature and relatively high humidity favor the development of the disease. The greatest incidence and mortality occur in new settlements situated in slightly cultivated forests. The clinical and epidemiologic characteristics of tick borne spring-summer encephalitis distinguish it from the Japanese and the St. Louis types, which are most prevalent during the dry, hot months of August and September. The authors list epidemiologic and experimental data that indicate transmission of the disease through ticks, especially *Ixodes persulcatus*. The transmission of the virus can be traced from infested larvae and nymphs to rodents or birds, which in turn transmit the virus to larvae and nymphs, thus completing the cycle. Every new animal species, including man, entering the forests is exposed to encephalitis. The possibility of producing artificial immunity in men is supported by the fact that convalescence from encephalitis is linked with a lasting immunity. There are prospects for the prophylaxis and treatment of encephalitis by serums obtained from convalescent or hyperimmunized animals. Serotherapy of encephalitis was studied in the endemic areas during the last five years. The serums obtained from convalescents or hyperimmunized horses produced favorable results in a number of cases when intraspinal injection of 10 to 15 cc. was supplemented with intramuscular injection of 30 to 50 cc. of serum. Immediate intramuscular injection of 40 to 50 cc. of serum is indicated for persons bitten by ticks in the endemic areas.

Colloid Cyst of Third Ventricle. E. W. Shannon.—p. 570.

Effects of Variations in Intracranial Pressure.—In the first part of this study Kahn is concerned with the effect of raised intracranial pressure on consciousness, which he studied in dogs. Distilled water was perfused into the anatomic central end of the common carotid artery, and observations were made on whether or not this procedure would render the animal comatose. Kymographic records were simultaneously taken of the respiration, the general carotid blood pressure, the cerebrospinal fluid pressure in the cisterna magna and the pressure in the brain tissue (intracerebral pressure). It was at first assumed that the pressure in the lateral ventricles was being accurately recorded by measurement of the cisternal pressure. The fallacy of this assumption was later demonstrated by some chance measurements of the intraventricular pressure. In subsequent experiments the intraventricular pressure was simultaneously recorded with a mercury manometer. Perfusion of distilled water into the anatomic central end of the common carotid artery resulted in elevation of the intracerebral and intraventricular pressures to levels above the cisternal pressure. When the intracerebral and the intraventricular pressure approached the level of the diastolic blood pressure, dire respiratory and circulatory effects were produced, ending in the death of the animal. Respiration first became labored and then stopped, and circulatory failure was preceded by pronounced

slowing of the pulse (heart rate) and terminal hypertension in 50 per cent of the experiments. The experiments reported in the second part of this paper were undertaken to study the mechanism involved in the production of these effects on respiration and circulation. It was found that the respiratory and circulatory embarrassment associated with high levels of intraventricular and intracerebral pressure could be relieved by ventricular drainage, which sharply lowered both the intraventricular and the intracerebral pressure. No circulatory or respiratory embarrassment occurred when both the cisternal and the intraventricular pressure were at high levels, but medullary embarrassment appeared soon after the cisternal pressure was lowered, the intraventricular pressure alone remaining high. In animals in which the intraventricular pressure was abruptly raised while measures were taken to keep the cisternal pressure low, the general tendency was toward a distinct slowing in heart rate. The hemodynamic effects in these experiments were not constant, the general tendency being toward a decrease in the blood pressure. The respiratory depression and the circulatory effects resulting from these abrupt increases in intraventricular pressure were eliminated by raising the cisternal pressure or by lowering the intraventricular pressure. The ill effects of increased intraventricular pressure are due to herniation of the medulla into the foramen magnum. This herniation was experimentally observed in dogs. The possibility also exists that the respiratory and circulatory effects were due to a herniation of the mesencephalon through the incisura tentorii. The fallacy of the cisternal pressure being regarded as a measure of the intraventricular and the intracerebral pressure when cerebral edema and/or the possibility of internal hydrocephalus exists receives emphasis from the results of the water perfusion experiments. In internal hydrocephalus consequent to severe cranial trauma, use of lumbar puncture as a means of relief of intracranial tension is invalid and contraindicated. Ventricular drainage is indicated for such a condition. Ventricular drainage, together with artificial respiration and administration of isotonic solution of three chlorides (infused into the central end of the common carotid artery), was efficacious in restoring respiration and increasing the blood pressure after severe medullary trauma in the water perfusion experiments.

Induced Resistance to Prolonged Sun Exposure.—Rudd investigated whether sunburn and its complications might be prevented by the use of small graduated doses of artificial ultraviolet radiation by the mercury vapor quartz lamp. He describes 3 cases as examples of the reaction to solar radiation after a series of hot quartz lamp applications of ultraviolet radiation. He stresses that such protection is particularly important to the person with light, tender skin or with any other form of sensitivity to solar radiant energy. If large numbers of service men needed this protection, mass treatments could be given with little cost or loss of time from duty.

Histidine Deficient Diet in Man.—Albanese and his collaborators studied the human requirement for histidine in 3 normal adult males submitted to an experimental diet consisting of fats, starches and certain fruits and vegetables of low

protein content which provided approximately 10 per cent of the daily nitrogen intake. The remaining 90 per cent was supplied as a histidine deficient casein digest. None of the three subjects developed clinical symptoms or changes in their blood chemistry or morphology. They all lost weight. The nitrogen balance remained positive throughout, and the excretion of histidine in the urine showed no reduction. The histidine deficient state was characterized by the appearance of an abnormal metabolite in the urine, a substance giving a green reaction with the Sharlit indican test. The results indicate that histidine is not essential for the maintenance of nitrogen equilibrium in the adult human being. The authors hesitate to conclude that histidine is unessential for man until further studies have clarified the picture. The loss of weight remains to be explained. The abnormal metabolite in urine in the histidine deficient period does not provide evidence of the essentiality of histidine. Apart from the question of the essentiality of the histidine for the adult is the question of the need of the growing organism for this amino acid.

Pneumoperitoneum in Treatment of Pulmonary Tuberculosis.—Crow reports 154 cases treated at the Georgia State Tuberculosis Sanatorium between August 1937 and June 1942. Pneumoperitoneum with consequent elevation of the diaphragm produces partial and often optimum compression of one or both lungs. Temporary phrenic nerve interruption prior to inducing pneumoperitoneum aids in securing greater elevation of the diaphragm. The majority, namely 122 of the 154 cases, were far advanced with a poor or hopeless outlook. There were 26 deaths during the treatment, 47 patients discontinued the treatment after a few refills and some could not be reached. Of the 77 cases in which treatments were continued, 10 were unimproved, 41 were improved and 26 were quiescent. Exudative lesions, particularly those in the middle third of the lung, showed the greatest amount of response. The effects on the lung and pleurae from pneumoperitoneum are much less likely to result in serious complications than are those of pneumothorax. A well established pneumoperitoneum will not reduce the apicobasal diameter of the lung more than 40 to 60 per cent and the total volume from 50 to 65 per cent, but the remaining partially inflated portion of the lung above the paralyzed hemidiaphragm is well splinted and the pressure against it is practically constant. The paralyzed hemidiaphragm, once it is well elevated, almost always remains practically stationary, regardless of the position of the patient.

Blast Injuries.—Hogan discusses some observations on 35 cases of blast injuries admitted to the hospital after Pearl Harbor. He recommends conservative treatment but states that recent perforation, gangrene of a segment of bowel and abscess formation demand surgical intervention. "War neurosis" and psychotic interludes have been attributed to exposure to concussions. Optic injuries, corneal and retinal hemorrhage, retinal

separation and presence of exudates have all been attributed to the effect of "blast" but have never been seen in animal experimentation. Injury to the ears is common. Underwater concussion may cause hemorrhage within any of the sinuses, sphenoidal as well as malar and frontal. Apparently injury to these sinuses may be of such violence as to fracture the bone. Fractures are supposedly due to the violent displacement of the limbs against some hard object rather than due to blast per se. Since the blast wave falls off in intensity very rapidly, every effort should be made to swim as far away from a source of concussion as possible, even a few yards theoretically constituting the difference between safety and fatal injury. The intensity of the concussion wave generated by explosions in air is greatly diminished in depressions, trenches and foxholes, so that "hitting the dirt" is a protection from blast as well as from the resulting shrapnel.

Effect of Quinones, Aldehydes and Ketones on Blood Pressure.—According to Oppenheimer and his associates there are five quinones which have more or less antipressor properties when tested on hypertensive mammals. These are (1) sodium rhodizonate, (2) sodium γ -thymoquinone sulfonate, (3) sodium beta-naphthoquinone-4-sulfonate, (4) 2,6-dichloroquinone and (5) 2-methyl-alpha-naphthoquinone. The first three of these proved to be toxic when tested on hypertensive dogs. Oral administration of sodium beta-naphthoquinone-4-sulfonate to 3 hypertensive dogs was ineffective. A search among the dialdehydes and diketones for effective antipressors on hypertensive rats and dogs has yielded one promising lead in 1,4-cyclohexandione. In the doses employed so far, 1,4-cyclohexandione has not produced toxic effects. Further studies are now in progress.

Dietary Protein and Physical Fitness in Temperate and Hot Environment.—According to Pitts and his associates recommendations for the daily protein intake of men who are doing hard physical work have ranged from 50 to 165 Gm. The present figure given by the National Research Council of 70 Gm. daily represents a compromise. For men working in hot environments recommendations are commonly made that protein intake be restricted on the ground that its high specific dynamic action imposes an unnecessary load on the heat dissipating mechanisms of the body. However, men who are accustomed to working in the heat prefer a diet containing liberal quantities of meat. Good examples are harvesters, miners and baseball players. The authors made a study of subjects

subsisting on three levels of protein intake. Particular attention was paid to the subject's physical fitness for work in temperate and in hot environments. Three subjects were studied under both temperate and tropical conditions while reclining, standing and marching. The urinary nitrogen excretion in grams per day averaged 18.5 during the high protein period, 9.5 during the low protein period and 12.9 and 13.5 during the normal periods before and after the experiment, respectively. There were minor changes in body weight, with a maximum during the high protein period. The plasma protein level showed no significant changes. Physical fitness under temperate conditions showed no changes attributable to dietary protein level. Performance of work in both hot dry and hot moist environments showed no changes attributable to dietary protein level. In both cases, however, improvements due to training and acclimatization were observed. Metabolism while reclining and while standing was not significantly different in the high and low protein periods. Metabolism while marching was slightly lower in the low protein period. However, this was a physiologically insignificant change. It is concluded that, even though protein does have a high specific dynamic action, the theoretical objections heretofore raised against a high protein diet in hot environments are unjustified. Protein intake may vary widely from 75 to 150 Gm. daily without effect on performance of intermittent work in the heat.

Development of Antibody Following Vaccination Against Pneumococci.—Hodes and his collaborators studied the production of pneumococcus mouse protective antibodies in the serum of a number of infants and children following vaccination with heat killed type I and type VI pneumococci. Most of the subjects were given the vaccine by intradermal inoculation. In a small group type I vaccine was administered by inhalation of a fine mist sprayed from a nebulizer. The patients were children admitted to the Harriet Lane Home or to Sydenham Hospital in Baltimore. The group was made up in part of children who had recently recovered from an acute infection and in part of those admitted to the hospital for study of some neurologic or metabolic disorder. The ages of the children varied from 2 weeks to 13 years. Among children over 2 years of age intradermal inoculation of a dose of heat killed type I pneumococci which did not cause systemic reactions or serious local reactions was followed in nearly every instance by an abrupt rise in serum mouse protective antibody titer. The level of antibody attained appears to be of the same order of magnitude as has been reported in adults following type I pneumococcus pneumonia treated with sulfonamides. The rise in antibody titer following vaccination persisted for at least several months. With few exceptions no rise in antibody titer following intradermal vaccination with type I pneumococci was

demonstrated among infants under 2 years of age. Inhalation by children over 2 years of age of a spray of killed type I pneumococci was followed in a few instances by a significant rise in mouse protective antibody titer. However, this method of vaccination was unreliable and cumbersome. Intradermal vaccination with type VI pneumococcus vaccine yielded equivocal results. Among children over 2 years of age a high pre-vaccination titer of mouse protective antibody against type VI pneumococcus was found much more often than against type I pneumococci.

*Measures to Prevent and Control an Epidemic of Ringworm of Scalp. G. M. Lewis, S. H. Silvers, A. C. Cipollaro, E. Muskatlitz and H. H. Mitchell.—p. 1327.

Measures to Control an Epidemic of Ringworm of Scalp.—Lewis and his associates state that an epidemic of *Microsporum audouinii* in New York City caused by *Microsporum audouinii* involving several thousand children has been spreading for more than a year. The report of a school nurse in this district regarding an unusually large number of children with infected scalps induced the district health officer to establish a diagnostic center to find the extent of the infection, to assist in diagnosis and to advise practitioners. All known infected children were asked to come to the diagnostic center for examination. They were examined under the filtered ultraviolet rays, a culture was taken and clinical records were kept. All child contacts were examined. New cases were soon found. The past treatment was appraised and, if unsatisfactory, the physician was told of the advantages of referring the patient to a skin clinic or to a dermatologist for the special care required. Each case was followed up by the diagnostic center until cured. Follow-up treatment had to be instituted in cases in which the x-ray epilation was incomplete. Absence from school became a problem, because it involved several hundred children in the district. Special classes formed for infected children functioned to the satisfaction of the children, the parents and the school and health authorities. After the patient was considered cured, two consecutive negative examinations by the diagnostic center, a week apart, were required before the child could return to school. Follow-up examinations were made at intervals of from two weeks to three months. Over a period of a little more than a year 432 children with *Microsporum audouinii* were registered at the diagnostic center. Of these, 411 had an infection with *M. audouinii*. By April 1, 1944 362 of these were known to be cured, while 70 cases were still active. New cases have decreased considerably. The authors make recommendations on measures to control the epidemic in New York City. The health department should lead by declaring the disease reportable, surveying all schools periodically, setting up diagnostic clinics in districts where the disease is prevalent and disseminating information to the general public. Filtered ultraviolet rays (Wood light) are essential in case finding and in determining when cure has taken place. Infections caused by *M. audouinii* should promptly receive the benefit of x-ray therapy.

*Migraine-like Syndrome Complicating Decompression Sickness. G. I. Engel, J. P. Webb, E. B. Ferris Jr., J. Romano, H. Ryder and M. A. Blankenhorn.—p. 304.

Emotional Albuminuria.—Alronheim noted that applicants for training as air cadets who after withdrawal of blood for a Kahn test had fainted or had felt faint almost invariably had considerable amounts of protein in the urine although a specimen of urine obtained prior to the withdrawal of blood had been free of albumin in a good percentage of cases. The regularity with which this phenomenon appeared in such persons as well as the increase in albumin in the second specimen following

a first specimen containing albumin suggested a relationship between the emotional upset precipitating fainting and the presence of protein in the urine. In order to substantiate this conception, the author made investigations on 1,000 young men between the ages of 17 and 26 who seemed to be perfectly healthy. Two specimens of urine were obtained during a period of about fifteen minutes, the second voiding being preceded by withdrawal of blood for a Kahn test. Only 446 of the 1,000 men gave negative reactions for albumin in both specimens; the other 554 men had positive reactions in one or both specimens, and in 504 of these albuminuria appeared after withdrawal of blood for the Kahn test. Of the 127 men who had fainted, only 3 had negative reactions in both specimens. The author thinks that the albuminuria was precipitated by emotional factors. There was no relationship between emotional albuminuria and the Schneider index. The intensity of albuminuria decreases with advancing age. Albuminuria in apparently healthy persons with a normal history is insignificant. It is possible that emotional albuminuria may be utilized as a test for emotional instability.

Migraine-like Syndrome Complicating Decompression Sickness.—According to Engel and his co-workers visual disturbances are common among subjects experiencing decompression sickness during exposure to simulated high altitudes in a decompression chamber. Blurring of vision or scotomas are usually followed by headache. This report is based on a series of 1,361 exposures of 155 subjects to simulated altitudes of 30,000 to 38,000 feet. Seventeen subjects experienced scotomas a total of 46 times; 36 instances occurred in 971 exposures at 35,000 feet, 9 in 383 exposures at 38,000 feet and 1 in an exposure at 30,000 feet. Anoxia was not present. It is apparent that these symptoms occurred repeatedly in some persons and not at all in others. The reaction always occurred after decompression sickness had developed, but it was unrelated to altitude; most often it developed five to thirty minutes after descent, but when it developed at altitude its course was uninfluenced by remaining at altitude or by descent. Although complicated by syncopal symptoms in some instances, the reaction was not related to syncope. Visual field studies revealed that the scotomas were homonymous, that they shifted rapidly in position, always moving peripherally, and that they were sometimes multiple. Headache, which was always contralateral to the scotomas, began when the scotomas had disappeared and was sometimes associated with nausea and vomiting. Electroencephalograms during two reactions revealed focal abnormalities in the cortex corresponding to the focal neurologic signs. The close similarity of the reaction to clinical migraine led the authors to inquire into the past history of migraine among the 115 subjects. A highly significant incidence of migraine headaches was found among the subjects susceptible to the reaction. These visual disturbances obviously represent a hazard during flying and landing operations. The fact that scotomas may exist for some time before the subject becomes aware of them and the frequency with which they seem to develop during descent suggest the possibility that they may be potentially responsible for landing accidents. Two steps would greatly decrease the incidence of those reactions among flying personnel engaged in high altitude work: (1) adequate preselection to eliminate persons susceptible to decompression sickness and (2) elimination of candidates with a history of clinical migraine unless their susceptibility to decompression sickness is low.

- *Meningitis in Children Refractory to Sulfonamides. R. Gross-Heisler and E. Davis.—p. 31.
*Pathogenesis and Clinical Symptoms of Tuberculous Meningitis. S. Engel.—p. 34.

Meningitis in Children Refractory to Sulfonamides.—Gross-Heisler and Davis point out that an impression prevails that treatment of meningitis other than tuberculous has been revolutionized by the sulfonamides. They describe 6 refractory cases they saw in the course of the last eighteen months. The ages of the children ranged from 3 months to 7 years. Two of the 6 patients had adrenal hemorrhage, and 1 of them fell into the category of the so-called Friderichsen-Waterhouse syndrome. Four patients with streptococcal and staphylococcal meningitis died despite intensive therapy with various sulfonamides. It is suggested that as soon as penicillin becomes available it should be used for such cases.

Pathogenesis and Clinical Symptoms of Tuberculous Meningitis.—According to Engel, tuberculous meningitis occurs most frequently in young children, and often in the first few months after the primary infection. Macroglandular caseation may pave the way for the secondary spread. The route of infection does not run directly from the primary complex to the meninges via the blood stream. The brain and plexuses in 13 cases of tuberculous meningitis in children have been investigated. Cortical foci and tuberculomas could not be found. Choroid plexus changes were present in every instance, but they were of a peculiar nature and not typical tubercles. The changes of the choroid plexuses suggest that they infect easily the ventricular fluid; they are numerous although minute by themselves but more likely to infect the fluid than solid tubercles or large caseous masses. Giant cells and caseation were present in advanced cases. Usually it is the final stage that presents itself at necropsy, but the author was able to observe a case in the initial stage. In spite of the early stage of the meningeal process the choroid plexuses showed the typical changes, but tubercle bacilli were abundant this time, contrary to the former findings. The choroid plexuses, it seems, breed initially an enormous number of bacilli, which drop from the decaying villi into the ventricular fluid and proceed from there through the natural communications to the basal spaces, thus producing basal meningitis. Tuberculous meningitis cannot be considered as an isolated occurrence in tuberculosis; it is always part of milary tuberculosis. The author emphasizes that the so-called classic picture of tuberculous meningitis applies only to a minority of cases among young children. In children of school age it is more frequent. It is advisable to use the dermographia test in doubtful cases, which is usually intense in cases of brain pressure.

Cushing's Pituitary Basophilism.—McLetchie reports the history of a man aged 32 who presented symptoms indicative of Cushing's syndrome. Necropsy revealed that here the pituitary basophilism was not associated with hypophysial, adrenal

or thymic tumor and that there was no adrenal hyperplasia. The abnormalities present in the anterior pituitary were (1) a conspicuous degree of basophil cell hyalinization, (2) an excessive degree of basophil cell vacuolation, (3) multifocal basophil cell vacuolation in the individual cells associated with excessive disappearance of granules and with the revelation of a refractile cytoplasmic envelop surrounding the vacuoles (cobweb vacuolation), (4) nuclei of the basophil cells normal but in many cells cobweb vacuolation associated with displacement of the nuclei to the periphery of the cells and with compression and scalloping of the nucleus by the vacuoles with numerous binucleate basophil cells, (5) the basophil cells increased in size and (6) the acidophil cells greatly reduced in size. These findings are contrasted with those in 2 other cases of basophilism, with those in nonbasophilism cases and with those of other recorded descriptions of the abnormal basophil cells of basophilism. The author stresses that the abnormalities of size and vacuolation found in the chromophil cells are (1) inconstant in basophilism and (2) not associated with a particular pathologic type of basophilism. The cobweb vacuolation and nuclear scalloping in the basophil cells is similar to what Severinghaus and others have interpreted as nuclear "blistering." It is suggested that the abnormalities of size and vacuolation in the chromophil cells represent a phase of reaction to hypogonadism and are of only secondary importance in the morbid process of basophilism. The author briefly discusses the correlation between the different pathologic types of basophilism. He also directs attention to the relation of the morbid process of Cushing's syndrome to the changes produced in rats fed on a diet containing a high proportion of Brassica seeds. He thinks that basophil cell hyperactivity is the essential abnormality of Cushing's syndrome and that basophil cell hyalinization is a cytoplasmic change resulting from hyperactivity.

Investigations on Sterility.—Sharman discusses certain selected aspects of sterility, namely (1) the estimation of tubal patency, (2) anovular menstruation as assessed by endometrial biopsy, (3) endometrial tuberculosis, (4) the causation of tubal occlusion, (5) seminal analysis and (6) the results obtained by a follow-up investigation. The observations are based on a consecutive and unselected series of 500 cases of primary sterility which have been followed up for several years and a number of more recent cases which have been the subject of particularized research. Estimation of tubal patency was done on 480 women, of whom about half had two or more insufflations. Insufflation revealed nonpatency in 38 per cent of the cases. Of 358 patients in whom biopsy was performed premenstrually, 6.4 per cent exhibited anovular cycles. Of 392 patients in whom biopsy was performed, 5.1 per cent showed unsuspected tuberculous endometritis. Seminal examination of 114 husbands revealed normal characters in 68.4 per cent, pronounced deficiency in 13.2 per cent and azoospermia in 18.4 per cent. Of 409 cases traced, pregnancy occurred in 116, i. e. 28.3 per cent. Pregnancy did not occur where anovular cycles or endometrial tuberculosis or azoospermia was present (with the exception of 2 cases of anovular cycles after treatment). In 152 of 293 sterile marriages infertility factors were found that would render pregnancy impossible or unlikely. The author thinks that if a greater number of cases had had endometrial biopsy and seminal examination performed there is little doubt that the infertility factors

of anovular cycles, tuberculous endometritis and azoospermia would have appreciably reduced the figure of 141 cases in which as far as investigation went, no reason was discovered for the infertility of the marriage. His studies on tubal patency by means of insufflation on a series of 1,063 revealed that true nonpatency exists in from 25 to 30 per cent of cases of primary sterility. The percentage of error in insufflation and in hysterosalpingography is about equal, but the error in the former is reliance on a single test, which error can be avoided by repeating the test, whereas the error in hysterosalpingography is in the reading of the plates and is not always remediable. In a further 491 consecutive and unselected cases of primary sterility 27 (5.5 per cent) have shown unsuspected endometrial tuberculosis. This gives a total incidence of 5.3 per cent in 883 cases. In cases in which gross tubal damage is not present, tubal occlusion is rarely due to gonococcal salpingitis or to congenital hypoplasia. Evidence is produced to show that blockage in a considerable number of cases is due to subclinical tuberculous salpingitis.

Hogben Pregnancy Test; Breeding of *Xenopus*.—According to Landgrebe and Sampson the South African clawed toad *Xenopus laevis* was first introduced as an assay animal by Hogben in 1930, who observed ovulation of *Xenopus* after injection of anterior pituitary lobe extract. The authors describe their experiences with the Hogben test. Of a total of 258 tests they were able to check 220 against ultimate clinical observations, and of these 218 were found correct. The 2 exceptions were patients with menopausal symptoms. The authors emphasize that the Hogben test for pregnancy, using the Scott technique for extraction of the urine, is as reliable as any other test, provided at least ten days elapse since the first missed period. Menopausal urines extracted by precipitation technique often give a positive Hogben test in the absence of pregnancy, but with the Scott extraction method the test gives a negative result in these cases and also gave a negative result in 2 pregnant patients showing menopausal symptoms at the time of the test. The Hogben test is more rapid and requires much smaller demands on laboratory routine than other tests. At 22 C. a result is obtained within eighteen hours, and the animals require feeding and cleaning only once a week. The test is much less expensive than the Friedman or the Aschheim-Zondek in both food and animal costs. Two toads are sufficient for each test if they are in good condition. Each toad was used over twenty-four times and still respond satisfactorily. Laboratory bred *Xenopus* toads can be used for the test and are capable of producing a second generation which will also respond to pregnancy urine extracts.

Heat Effects in British Service Personnel in Iraq.—Morton divides heat effects into heat syncope, heat exhaustion and heat hyperpyrexia, because the clinical picture is as a rule clearcut and the prognosis and treatment are radically different. Syncope occurs in temperate climates, in hot stuffy atmospheres and also in heavily overladen soldiers on the march. It is a temporary cardiovascular collapse which, like other faints, may progress to severe prostration with giddiness, a small soft fluttering pulse, shallow breathing, dilated pupils, a cold skin and subnormal temperature. The patient is bathed with a cold clammy sweat, and severe headache and mental confusion may follow. Death may occur in cases of heart disease. Treatment consists in dorsal decubitus in a cool place, the loosening of tight clothing and the bathing of the face with cold water together with the application of ammonia to the nostrils and a small dose of sal volatile. Electrolytic imbalance and dehydration

tion appear to be of primary importance in the genesis of heat exhaustion. The lean, spare type with a low systolic pressure is particularly prone to heat exhaustion. The quantitative estimation of the urinary chlorides is a simple and reliable test in the differential diagnosis of these cases, and sodium chloride and glucose are a safe and effective remedy. If intravenous therapy is indicated, this must be controlled by charting the intake and output and estimating the hemoconcentration; otherwise there is a risk of pulmonary edema. The prognosis in heat exhaustion is excellent, provided the condition is recognized in time and adequately treated. Heat hyperpyrexia is always a grave syndrome: the mortality is usually at least 30 per cent and may be considerably more. Alcohol and age are accessory and adverse factors, and the condition is more frequent in the fat and plethoric. The essential factor is the failure of the heat regulating center with the suppression of sweating, although in the more protracted cases it is probable that an autointoxication is responsible for the prolonged pyrexia. Thermantidote measures and the nursing of these patients in artificially cooled wards are the basis of treatment. Ample cool drinking water containing 10 grains (0.65 Gm.) of sodium chloride to the pint, together with a total consumption of at least 1 ounce (30 Gm.) of sodium chloride a day is a paramount necessity in all endemic areas during the hot weather. The provision of air conditioned or artificially cooled wards in hospitals in endemic areas is essential.

Spinal Varicosities.—According to Uehlinger and Gsell, dilatation and serpentinization of the veins of the spinal cord may cause changes in the medulla and irritation of nerve roots. Clinically it becomes manifest in two syndromes: (1) as an apoplectic form and (2) as a neuralgic paralytic form. The authors describe 2 cases observed by them during the past year. The first belonged to the group of juvenile apoplexy. The patient, who died at the age of 28, had a first apoplectic attack after a scare at the age of 18 and a second fatal stroke ten years later, both from complete well-being. The first acute spinal apoplexy resulted in flaccid tetraplegia, singultus, priapism, impairment of voluntary urination and defecation and in disturbance of sensibility. Meningitic symptoms were absent. The clinical course was that of a typical hematomyelia in the lower cervical cord with perforation of the hemorrhage into the subarachnoid space. The paralytic symptoms commenced to regress after a few hours. The attack terminated in complete restoration of motility and sensibility of the left arm and the legs, but in the right arm and shoulder region an atrophic paresis remained. After an interval of ten years a second spinal apoplexy suddenly developed. The attack was followed by death within ninety minutes. There was pulmonary edema but again no loss of consciousness. Necropsy explained both attacks as acute hematomyelia, originating in a varicose network on the cervical spinal cord. Whereas the first attack had destroyed only some segments of the right lower cervical spinal cord, in the second attack the hemorrhage extended upward and downward with perforation into the ventricle and the central canal of the spinal cord. The second patient, a man aged 48, experi-

enced acute pain in the lumbar region which developed into a syndrome of radicular sciatic neuritis first unilaterally and later bilaterally; death was caused by transverse lumbar myelitis. Necropsy disclosed spinal varicosities near the cauda. Spinal varicosities may be a partial manifestation of a status varicosus or it may be limited to the spinal cord. The condition is more frequent in the male than in the female, as was demonstrated by Globus and Doshay in 1929. The apoplectic form usually appears earlier in life than the neuralgic paralytic form. The presence of extraspinal varicosities, such as varicose veins or hemorrhoids, may be of help in the diagnosis. Laminectomy with spinal decompression may lead to the arrest or even the regression of the symptoms of spinal varicosities. Observations so far do not indicate resection of the spinal varicosities, since the effect of this intervention cannot be foreseen.

Nephrotic Hypertension Syndrome in Diabetes and Kimmelstiel's and Wilson's Inter-capillary Glomerulosclerosis.—Auroi describes 4 cases of women 64, 54, 45 and 60 years of age with diabetes, presenting Kimmelstiel's and Wilson's nephrotic hypertension syndrome. The condition in these and in similar cases described in literature is anatomically characterized by a peculiar primary independent hyalinization of the glomeruli. It may remain clinically latent, or albuminuria, arterial hypertension with its sequels in the circulatory apparatus and renal insufficiency, i. e. the common picture of glomerular disease may be presented, depending on the degree and extent of the lesions. The nephrotic syndrome (hypo-proteinemia and edema) should be considered coordinated or subordinated to the glomerular process, in correspondence to the findings in diffuse glomerulonephritis with nephrotic type of edema. Diabetes associated with advanced age may safely be assumed to be the etiologic factor. There were only a few exceptional cases in which the intracapillary glomerulosclerosis was not associated with diabetes. Latent diabetes, however, or aglycosuric diabetes resulting from an increase in the renal threshold was probably present in those instances. A masked diabetes should be watched for in individuals of advanced age presenting the nephrotic hypertension syndrome. The finding of intracapillary glomerulosclerosis at necropsy strongly suggests the premortal presence of diabetes. The course of the fully developed intracapillary glomerulosclerosis is rapid, and death from cardiac insufficiency, uremia or apoplexy will occur within two to three years.

- *Therapy of Parkinson's Syndrome by Vitamin B₆ (Pyridoxine). A. Sanabria and L. A. Muro.—p. 125.

Vitamin B₆ Therapy of Parkinsonism.—Sanabria and Muro administered vitamin B₆ to 11 patients with parkinsonism. The drug was given intravenously on ten consecutive days in daily doses of 50 mg. The treatment was continued after the ten days only on patients who improved during its administration. It was given intravenously every other day in doses of 50 mg. and also by mouth in 10 mg. doses on the days on which the drug was not injected. By the end of the treatment tremor was almost completely controlled, and muscular rigidity and muscle tone were greatly improved in 4 cases. Walking was regained in 1 of the 4 cases. Tremor alone was controlled in 1 case. No effect from the treatment was observed in 6 cases. Sialorrhea was not affected in any case. Best results were obtained in early cases. The fact that the drug is expensive makes its use less available than that of the alkaloids of belladonna.

Book Notices

Clinical Tropical Medicine. By Twenty-Seven Authors. Edited by Z. Taylor Bercovitz, M.D., Ph.D., F.A.C.P., Assistant Clinical Professor, New York Post-Graduate Medical School, Columbia University, New York. With foreword by Wilbur A. Sawyer, M.D., Director, International Health Division, Rockefeller Foundation, New York. Cloth. Price, \$14. Pp. 957, with 141 illustrations. New York & London: Paul B. Hoeber, Inc., 1944.

This attractive volume is a useful addition for any medical library. It is handsomely printed, and there is an agreeable and rare paucity of typographic errors. The form is monographic and the authors' list includes many accepted authorities such as C. F. Craig, Lee Foshay, Howard Fox, A. W. Grace, A. V. Hardy, G. W. McCoy, K. F. Meyer, Morris Moore, Henry Pinkerton, J. F. Siler, F. L. Soper, E. B. Vedder and W. H. Wright, to mention only some.

The volume is too large for easy handling, and its values are spotty. It might have been improved by condensation of certain subjects such as rabies, psittacosis and tularemia, and by omission of such subjects as poliomyelitis, smallpox, varicella, typhoid, epidemic encephalitis and trachoma. A few sections could well be amplified and brought up to date. In the latter group are the short, almost fragmentary sections on personal hygiene and sanitation in the tropics, where specific recommendations would be of more value than trite generalizations. Mosquito control is barely mentioned in this section. Acclimatization, environmental effects of geography and social climate and medical geography are not discussed and hardly clearly mentioned. Yet on these will depend much of what mankind accomplishes in the future in regions of warm climate. Problems of housing, food supply and future transport and communications could have their medical groundwork laid now, and this would have been within the field of a monographic review of tropical medicine.

More in detail the following comments occur to the reader. The discussion of sprue, beriberi, pellagra and scurvy by E. B. Vedder is splendid. It is preceded by a clear, comprehensive and up to date description of the vitamins. Outside of trichina, filaria and schistosomes, helminths are well covered as to epidemiology, prevention and treatment. Trichinosis is poorly covered, especially in respect of subclinical infection, epidemiology, geography, animal sources, digestion of biopsy material and suspected meat, and prophylaxis by refrigeration. The space allotted to *Wuchereria bancrofti* is far less than that for trichinosis. This section is poor, as is also the sketchy review of schistosomes.

While the biology and diagnosis of amebiasis are discussed at length, the bacteriologic diagnosis of bacillary dysentery is only mentioned and not described. The review of treatment of bacillary dysentery is sketchy and incomplete without critical comparison of sulfonamide drugs. The paragraph on transfusion could better have been omitted. The special diet list and instructions are redundant, unnecessary and inaccurate, while the advice on bacteriophage is equivocal. In fact, the section on the treatment of bacillary dysentery is poor and not up to the level of most chapters in the book.

The discussion of cholera by Joseph F. Siler is unusually satisfactory. Malarial sections in general are diffuse, not clear, often inexact and ambiguous, and the presentation of distribution is quite inadequate. Reference is made to Sir Andrew Balfour as if he were still alive in Khartoum. In connection with the differentiation of malaria and kala azar, it is scarcely correct to say that it is by microscopic examination of the blood alone. Some odd spellings have slipped by, as "comatous" for "comatose" and (on page 3) "aescophagostomum" for "oesophagostomum." One questions the usefulness of a clinical classification of subtertian malaria by symptoms rather than by underlying pathologic changes, and it is not allowable to refer to gametocytes as developing from schizonts.

The treatment of malaria should be revised and better organized. Many would not agree with the flat rules that any person from an endemic area should receive 10 grains daily of quinine for eight weeks, that sufficiently long use of quinine will eliminate "malarial infections" or that "when it is impossible to administer quinine by mouth, atabrine should be used."

There is no discussion of varying objectives of treatment under different conditions, as for instance various military and civilian requirements, or of varying requirements of different plasmodia or of utilization of malarial immunity in treatment. In spite of the aforementioned quotation, the statement is also made that all who "return by ship from tropical or highly endemic areas" should receive atabrine 0.1 Gm. thrice daily for five to seven days and then 0.1 Gm. daily for two months. Discussion is lacking of the basic pharmacology of the antimalarial drugs and of the relation of transfusion to malarial transfer. Mosquito control and malaria prophylaxis (suppression) are sketchy and quite inadequately presented. Reference is not made to species attack or to spraying, and final advice is given that "people who live in malarial districts should not leave their houses between sunset and sunrise."

A distorted clinical picture follows mention of gallstones as a complication of blackwater fever. Under trypanosomiasis, synonyms of "Bayer 205," e. g. "germanin," should be given. American trypanosomiasis by this time should certainly be divorced completely from thyroid disease and the chapter brought within range of present day knowledge.

The date of publication of the volume should have included the final demonstration of the sandfly vector of leishmaniasis by Swaminath, Shortt and Anderson in 1942. American leishmaniasis is not clearly presented, nor the geographic spread of oriental sore. Howard Fox, in valuable reviews of pinta and yaws, carefully but firmly pays his respects to Admiral Butler while maintaining the difference between yaws and syphilis.

The discussion of the rickettsioses by Pinkerton is clear and of sound clinical value. Soper on yellow fever has given an authoritative and useful survey. The clinical discussion of mycoses by Morris Moore is excellent, as are also the short chapters on snake bite by J. A. Oliver and Dudley Jackson. The material on noxious arthropods is scattered and not easily assembled for use, and in general the descriptions are not sufficient for rough identification.

This volume is therefore of variable and spotty value. The major part is excellent, well written by authorities. Other parts fall short of this level. For the purpose of a monographic clinical presentation of tropical medicine it needs additions, deletions and some rewriting, as already noted.

Chemical Analysis: A Series of Monographs on Analytical Chemistry and Its Applications. Editorial Board: Beverly L. Clarke, I. M. Kolthoff and Hobart H. Willard. Volume I: *The Analytical Chemistry of Industrial Poisons, Hazards and Solvents.* By Morris B. Jacobs, Ph.D., Senior Chemist, Department of Health, City of New York. Second revised reprint. Cloth. Price, \$7. Pp. 661, with 110 illustrations. Volume III: *Colorimetric Determination of Traces of Metals.* By E. B. Sandell, Ph.D., Assistant Professor of Analytical Chemistry, University of Minnesota, Minneapolis. Cloth. Price, \$7. Pp. 487, with 73 illustrations. New York: Interscience Publishers, Inc., 1941.

Physicians encountering industrial health problems and especially those who are concerned with the prevention of industrial disease will find volume I valuable. Designed primarily to summarize practical applications of analytical chemistry in industrial hygiene, it also serves as a reference work on the occurrence of hazard, physical properties, toxicity and physiologic response and methods of detection of a large number of substances currently employed in modern industrial production. The monograph is well organized. The analytical methods are clearly stated and well supported by adequate references to the original literature. The introductory portion of the text is devoted to the general consideration of industrial hygiene and industrial poisons, sampling, gasometry and methods for the handling and examination of dusts. Subsequent chapters give information on silica, various metals, compounds of sulfur, phosphorus and nitrogen, oxygen and ozone, halogen compounds, carbon monoxide, carbon dioxide, hydrocyanic acid and cyanogen. Almost half of the book is utilized to present the properties, actions and modes of estimation of some one hundred and twenty-five organic substances, including industrial solvents, raw materials of manufacture and chemical warfare agents. An appendix contains useful tables, among which are several concerned with the probable safe concentration limits of exposure for gases, vapors, metallic and other dusts and fumes.

Volume III was designed to present a number of useful modern methods for the determination of small amounts of

each of forty-five different elements, exclusive of the information provided on the rare earth elements. In the first part of the text a critical discussion of colorimetric trace analysis is given. General methods for the separation and isolation of small quantities of the elements by chemical and physical means are outlined and evaluated. There follows a logical treatment of colorimetric and spectrophotometric measurements, with discussion of their place in the estimation of trace elements. Nineteen colorimetric reagents which find practical application in trace analysis and the nature of their reaction types and specificity are described in the final chapter of this general part of the book. The remaining three fourths of the text is devoted to the discussion of the various elements encountered in practical trace analysis. Each element is considered in detail—separations, methods of determination and application of the methods given are presented. Although colorimetric methods for the determination of substances have been frowned on by some investigators as being peculiarly subject to error, such methods prove to be invaluable in the hands of investigators who take the trouble to consider the underlying principles involved. An understanding of the limitations of colorimetric and photometric technics, coupled with knowledge of the fact that annoying but surmountable interferences may occur in many chemical reactions, permits of a wide range of their application. This book on trace metal determination is well written; it contains many carefully chosen references to the original literature and to earlier compilations in the field of colorimetry. The author has made judicious use of structural formulas, tables and charts to clarify the subject and to illustrate the practical limitations of many of the procedures. Although the book is not directed specifically to the needs of the clinician, it should prove to be of great value to those investigating the influence of trace elements in biologic phenomena.

The Hogg Foundation Reports: A Summary of Three Years Work—A Forecast of Next Steps. Robert L. Sutherland, Director, Hogg Foundation for Mental Hygiene. Paper. Pp. 32, with 4 illustrations. Austin: Hogg Foundation for Mental Hygiene, University of Texas, 1944.

This pamphlet describes the work of the first three years of the Hogg Foundation and presents plans for the future. Established through a gift of Will Hogg to the University of Texas, the foundation is dedicated to an improvement of mental hygiene in Texas by bringing together knowledge of sound principles of human development from the specialized fields of psychiatry, physiology, psychology and sociology and applying them to the "conditions of growth and development of all persons." The work of the foundation is carried on at three levels. The first level consists of lectureships "to carry the basic principles of mental health to many fields of interest as well as to many localities." At the second level the foundation provides planned instruction in mental hygiene for professional leaders who are engaged in, or are preparing to enter, human relations work. This includes the professions of medicine, nursing, school guidance, industrial personnel, case work, group work and the ministry of the religious counselor. At the third level the foundation is assisting in the establishment of diagnostic clinics to detect the signs of maladjustment at an early stage and provide treatment. The foundation plans to continue and expand its work and will carry out studies and provide assistance in the adjustment problems of the returning veterans. The program of the foundation is educational, stressing prevention and early diagnosis and treatment. Such an approach to health problems deserves further development in other fields of health. It is especially important in the field of mental health, of which our wartime experiences have made us acutely conscious.

Guiding the Normal Child: A Guide for Parents, Teachers, Students, and Others. By Agatha H. Bowley, Ph.D. With a foreword by D. R. MacCallman, M.D. Cloth. Price, \$3. Pp. 174. New York: Philosophical Library, 1943.

This small work by an English psychologist is designed primarily for teachers but is also intended for parents. The dynamic psychology now current in our psychiatric thinking offers the theoretical background for the author; the Child Guidance Center and Nursery School provide the material for her observations of children and her practical and clinical

presentations. The book will appeal more to educators and to psychologists than to parents. It is authentic in content but not too well organized. An abundant but not too discriminating bibliography is offered. The typography is easily readable; the unappealing format is perhaps to be attributed to wartime restrictions in book making. A glaring error in the table of contents startles the reader.

The Art and Science of Nutrition: A Textbook on the Theory and Application of Nutrition. By Estelle E. Hawley, Ph.D., and Grace Carden, B.S. Second edition. Cloth. Price, \$3.75. Pp. 668, with 139 illustrations. St. Louis: C. V. Mosby Company, 1944.

In this edition the inclusion of the most recent advances in the science of nutrition constitutes the main addition. The present status of knowledge of vitamins and minerals is concisely and accurately recorded, with the recommended daily allowances of these elements listed. The material in the book is developed on the foundation of a thorough but direct and readily understandable presentation of the fundamental facts of normal nutrition. The abnormal states of vitamin deficiencies are gone into in some detail, with numerous excellent pictures demonstrating these conditions. The nutritional principles set forth in earlier chapters are later applied to the feeding of various population groups, from the family as a whole to its specialized members, such as infants, growing children and the aged. Consideration is given to the special physiologic requirements of pregnancy and obesity. Probably the strongest section of the book is that covering diet therapy. Here discussion is found of the dietary indications for every possible condition in which benefit may be expected from the use of a suitable diet. In addition to a statement of the principles involved, simple directions are given as to what foods to use and what to avoid. In many cases the discussion goes beyond the limits of nutrition by going into the etiology of the diseases and their symptomatology and differential diagnosis. The wisdom of this is questioned. The last section deals with the art of nutrition in the way of preparing foods for consumption. This part of the book consists of menus, lists of foods and reference tables of food values. Its didactic form leaves much to be desired for an artful presentation of the subject or the foods. It contributes little to the interest in the book, although it may be of value for reference. Altogether the entire work with its profusion of illustrations can be recommended as an excellent textbook for the instruction and practical use of nurses as well as practicing physicians.

A Textbook of Inorganic Pharmaceutical Chemistry. By Charles H. Rogers, Sc.D., Dean of the College of Pharmacy and Professor of Pharmaceutical Chemistry, University of Minnesota, Minneapolis. Third edition. Cloth. Price, \$7.50. Pp. 704, with 52 illustrations. Philadelphia: Lea & Febiger, 1943.

The earlier editions of this textbook, appearing in 1930 and 1936, served as commentaries on the inorganic compounds which were to be found as official drugs in the tenth and eleventh editions of the United States Pharmacopeia and in the fifth and sixth editions of the National Formulary. The present volume has been revised to include all the inorganic salts of organic acids, as well as the inorganic substances recognized by the U. S. P. XII and the N. F. VII. As in earlier editions, the elements are considered in an order which makes the volume suitable as a textbook on inorganic chemistry. The history and occurrence, physical and chemical properties, qualitative tests, method of preparation and, in addition, pharmacologic action and general uses of the substances are included. This edition is well printed, and excellent use is made of chemical equations in the presentation of chemical properties. It might be argued that some additional material could well be added to certain chapters; for example, the chapter on gold and gold compounds might include a discussion of the chemistry and pharmacologic action of sodium gold thiosulfate. Designed primarily for the student of modern pharmacy, the book, nevertheless, should serve as a useful source of information for physicians who are interested in gaining familiarity with the history and chemistry of many of the drugs which they may daily prescribe.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TOPICAL APPLICATIONS OF SULFONAMIDES AND PENICILLIN

To the Editor:—What are the therapeutic possibilities in injecting suspensions of sulfadiazine, sulfathiazole or other sulfonamides directly into or around the sites of localized infections? Mention of such treatment has not been found in available literature. It is understood that the soluble sodium sulfonamide preparations employed for intravenous therapy could not be used in this manner because they are intensely irritating and cause tissue necrosis. However, the less irritating and less soluble sulfonamides injected in suspension might be more valuable because of their low solubility, the gradual solution of the crystals in the tissues producing prolonged high concentration in the area of the infection. It is conceivable that administration of sulfonamides by this route might have value in many localized infections including furuncles, carbuncles, felon, cellulitis, gas gangrene, suppurative arthritis and infected cysts. Perhaps by this method effective concentrations of sulfonamides might be brought to bear on such infections, while their relative concentration in the blood and the rest of the body would be low, thus avoiding the unfavorable reactions of large doses of the drugs by mouth. Might it be indicated to attempt to develop preparations of sulfonamides especially for this use, the desirable characteristics sought being a minimum amount of irritation to the tissues and the property of dissolving into the tissues slowly? 1. Has there been any work along these lines of either experimental or clinical nature, and if so what were the results? 2. What are the drawbacks and contraindications? Specifically, would the injection of small amounts of crystalline sulfathiazole or sulfadiazine suspended in water or isotonic solution of sodium chloride produce local irritation or necrosis? 3. If the procedure is not contraindicated, what dosage and form of administration is suggested for typical cases? If this method of approach has not already been tried and found worthless, what are its possibilities? Does it justify a program of investigation? Could penicillin be administered in a similar manner?

M D, California

ANSWER.—1. There apparently is no extensive series of published data relating to experimental or clinical investigations of this type. However, suspensions of sulfanilamide in isotonic solution of sodium chloride have been injected into infected pleural cavities. This procedure has been associated with some improvement. Likewise, such suspensions have been introduced into the peritoneal cavity where suppuration has been present. Although observations have not been too extensive, the results appeared to be favorable. Suspensions of sulfanilamide and sulfathiazole have been used in the nasal and aural cavities with apparent clinical improvement.

2. It is difficult to see how such a procedure would be of much benefit in the therapy of soft tissue infections such as carbuncles, cellulitis or infected cysts. The main object in therapy is to keep such infections localized, and it is now the consensus of many authorities that this can be best accomplished by oral or parenteral administration of adequate doses of sulfadiazine or sulfathiazole. The pendulum appears to be swinging away from the routine topical application of the sulfonamides in the therapy of localized, suppurative lesions. The main objection to the routine injection of sulfonamide suspensions is that it might not accomplish the anticipated therapeutic response. Such a procedure might well cause some local irritation, but no considerable degree of necrosis.

3. Since oral or parenteral sulfonamide therapy combined with adequate surgical drainage appears to produce desired therapeutic responses in comparison with the local use of the drugs, one cannot become too enthusiastic about the proposed investigation.

Now that penicillin is becoming available in larger quantities, more profitable lines of investigation are opening up. Solutions of penicillin have been introduced into the pleural cavities in instances of suppurative infections with remarkable clinical improvement. It is unlikely that the injection of penicillin solution into soft tissue infections will offer any advantage over systemic treatment.

VITAMIN A FOR ACNE VULGARIS

To the Editor:—A dermatologist has prescribed 100,000 units of vitamin A to be taken daily for six months for the treatment of acne vulgaris. Is it dangerous for an 18 year old girl to take such large amounts of vitamin A for six months? What is the efficacy of such treatment?

M D, Tennessee

ANSWER.—A hundred thousand units of vitamin A daily seems a moderate dosage. Lehman and Rapaport (THE JOURNAL, Feb. 3, 1940, p. 386) mention a single dose of 2,000,000 units given as a test for visual deficiency, and the authors themselves gave from 100,000 to 300,000 units daily for months to children with no bad effect. Harm from overdosage does not

seem likely. Long continued treatment is necessary in most cases to obtain benefit from vitamin A. Its value in acne vulgaris has not yet been proved to the satisfaction of dermatologists generally. An excellent paper on the subject is that of Straumfjord (Northwest Med. 42:219 [Aug.] 1943). He reports that 36 patients were entirely freed from lesions and 43 others were cleared except for an occasional papule or pustule. Of 28 of those wholly freed, 64 per cent were cleared in nine months or less and 89 per cent in twelve months or less. Some remained well without further dosage of the vitamin; others relapsed and had to resume the vitamin consumption. There were more of the latter group among those who had cleared comparatively early. Thus it is seen that the treatment is slow but harmless, and it is successful in a good percentage of cases—even some that had failed to improve on other methods of treatment. Scarring acne should receive other more rapid methods of treatment which can well be combined with the vitamin method.

TREATMENT OF WHOOPING COUGH

To the Editor:—What, if any, value has Souer's vaccine following exposure to pertussis or during a current epidemic? A pertussis vaccine is available through the state laboratory service and is widely used by the local pediatricians in the treatment of pertussis. To date I have advised the parents of the children whom I have seen as follows: Isolate their children from exposure to the disease if possible. If they should develop symptoms, have the therapeutic series of treatments with the state provided vaccine; if not, wait until the epidemic subsides and then have the prophylactic series, using Souer's preparation. I have based this advice on the assumption that it would take three to four months to develop immunity using Souer's vaccine. In the meantime, if the children should develop symptoms, would they be sensitized to the extent that use of the therapeutic vaccine would be ill advised?

M D, New York.

ANSWER.—It is doubtful whether any pertussis vaccine is of value as a therapeutic agent; i. e., in the treatment of the disease. The Souer vaccine, made with human blood, can be used repeatedly, if necessary, without any risk. Its chief use is as a preventive agent, especially in infants past 7 months of age.

In treatment of infants and frail young children ill with the disease, either after definite exposure or at the onset of definite symptoms, two doses of the human hyperimmune (lyophilized) pertussis serum may be beneficial. It is prepared by the Serum Exchange at the University of Philadelphia and is by far the most desirable therapeutic product available. The subject is discussed by Brennemann in his Practice of Pediatrics, volume 2, chapter 34.

"ENLARGED PORES" OF SKIN

To the Editor:—A woman aged 19 had been working in a defense plant. She had been exposed to excessive heat over a period of six months. She stopped working because the pores of her face (on the forehead and the tip of the nose) had become excessively enlarged and remained that way. Many preparations have been used in the last five months but to no effect on these enlarged pores of the skin, especially of the nose.

J. T. Nardo, M D, Somerville, Tenn

ANSWER.—The texture of the skin can be changed by age, disease or alterations of the secretions of the endocrine glands. Sweating is a normal function of the skin, and no evidence has been found that excessive sweating can cause enlargement of the hair follicles. Efforts to lessen the size of the pores by external applications are not likely to succeed. Patting the skin or the application of heat, according to H. G. Goodman (Cosmetic Dermatology, New York and London, McGraw Hill Book Company, 1936, p. 217) causes a temporary swelling of the skin and lessening of the size of the follicular openings. Astringents have the same effect in a greater degree by causing a slight inflammation. Even so vigorous a measure as skin peeling is likely to result in only temporary effect. Unless the large pores are actually comedones, the use of roentgen rays to lessen the activity of the sebaceous glands seems hardly justifiable.

INJECTIONS FOR SPRAINS

To the Editor:—I wish to comment on the discussion of "Local Anesthetic Injections for Sprains" in Queries and Minor Notes in The Journal, July 15, 1944. The purpose of injecting painful areas in sprains with a local anesthetic is not only to give immediate relief from pain but, what is more important, to relieve spasm of the surrounding tissues, which always occurs following injury. The mere injection of the ligaments around a joint cannot repair the damaged tissues. Following the injection, the area should be massaged in order to avoid accumulation in any one area and pressure necrosis from procaine. Recovery is expedited by good support of the joint with proper strapping, which will support the joint and enable the patient to walk freely. This in turn will encourage lymph flow and return. For example, in the ankle joint, flexion and extension or the forward and backward movements of the tibia are permissible, however, the rocking of the foot or ankle from side to side will stretch the afflicted lateral ligaments, which aggravates the injury. The method should not be condemned unless it is properly executed. The injection treatment is an adjunct and not a substitute for the practice of good surgery in the management of sprains.

RELOCATION OF PHYSICIANS

A PREREQUISITE TO BETTER MEDICAL CARE

CHAIRMAN'S ADDRESS

JOSEPH W. MOUNTIN, M.D.

Medical Director, U. S. Public Health Service

WASHINGTON, D. C.

Most of the current controversy in respect to medical care centers on methods of paying for service rather than on how the service is to be provided. These are separate but intimately related questions. The former is likely to be determined finally as a political issue, while the latter should be solved by the medical profession itself. Since the physician is the central figure in any scheme of medical service, primary consideration must be given to placing physicians in areas where they are most needed. Although persons residing in certain localities and belonging to underprivileged classes of the population have illness rates somewhat higher than those of people living under better circumstances, a straight population enumeration gives a fairly accurate measure of the relative needs for medical service in one area as contrasted with another. Unfortunately, wealth more than population normally determines the number of physicians to be found in the average community.

As compared with recent years, the distribution of physicians appears to have been more equable at the beginning of this century. According to tradition and such data as are readily available, it would seem that physicians then were to be found in every hamlet and even at some of the crossroads. Since that time there has been a progressive decline in the numbers of rural physicians and an increasing tendency for more of the recent graduates to locate in the larger urban communities. Moreover, a simple numerical count does not tell the whole story. Rural physicians are much older, and hence their expectancy in years of professional service is less than for those in centers of population.

For purposes of this discussion, the year 1940 is taken to represent normal peacetime conditions. War abroad had stimulated the domestic economy to a point where recovery from the depression was nearly complete. Furthermore, the two basic documents on which this paper is based, the 1940 United States Census Reports¹ and the directory of physicians,² were current for that year. Data for these publications were gathered before the normal way of life had been materially disturbed by the national Selective Service and training program.

From the States Relations Division, Bureau of States Services, U. S. Public Health Service.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

1. Sixteenth Census of the United States, 1940 Population: First series, number of inhabitants, United States summary, United States Department of Commerce, Bureau of the Census, 1941.

2. American Medical Directory, ed. 16, Chicago, American Medical Association Press, 1940.

In 1940 there were 175,000 physicians listed in the directory or 1 for each 751 persons in the continental United States. Among the several states the number of physicians varied from 1 for every 492 persons in New York State to 1 for every 1,459 in Mississippi. However, about 10,000 of the total group were designated as retired and 4,800 as in federal service. This reduced the physicians available for local service to approximately 160,000. Of this number nearly 15,000 occupied full time positions in institutions, 6,000 were teaching or combining hospital and teaching work, and approximately 2,600 were employed full time in state and local health departments. With few exceptions the others, numbering about 136,000, were engaged in private practice.

From the standpoint of capacity to serve, the count of 160,000 physicians available for local service is somewhat misleading. This enumeration includes medical personnel of all age groups; however, Ciocco and Altman³ have found that the service performed by a physician in private practice varies decidedly with age. The activity of an average private practitioner reaches a peak of approximately 170 patients per week in the age interval between 35 and 40 and continues almost on a plateau for a comparatively few years. After that the physician faces with advancing years a continuous decline in patient load which, without doubt, is closely correlated with capacity to serve. Moreover, the practice of a young physician just beginning his career undergoes a building up period of several years during which he sees fewer patients than he could handle, simply because he has not yet won the confidence of the community.

Curve A in the chart illustrates the service cycle experienced by an average active physician and emphasizes the necessity for establishing criteria other than simple numerical counts of physicians for estimating the professional resources of a community. From this curve appropriate measures of a physician's capacity for service at each year of life may be estimated. Such index values represent approximate service equivalents⁴ of physicians at different ages. On this basis an average physician of 26 renders service equal to approximately one fourth of that which he will render in his fortieth year. The fraction increases to three fourths when he is 31 and reaches 100 per cent before he is 40. The decline of activity with advancing age is somewhat more gradual. The fraction falls to three fourths when he is 53, one half at 64 and one fourth at 75 years. Naturally this does not imply that all physicians operate

3. Ciocco, A., and Altman, I.: The Patient Load of Physicians in Private Practice: A Comparative Statistical Study of Three Areas, Pub. Health Rep. 58: 1329-1351 (Sept. 3) 1943. Also unpublished data from Ciocco's and Altman's study showing numbers of patients seen per week by physicians in five year age intervals.

4. Pennell, E. H.: Location and Movement of Physicians—Methods for Estimating Physician Resources, Pub. Health Rep. 59: 281-305 (March 3) 1944. Pennell defines service equivalent as "the decimal fraction obtained by dividing the average weekly number of patients seen by a physician of designated age by the corresponding number seen by a physician at the peak of his career."

at the service capacity indicated. These constants are presented as approximations for the average active practitioner. When for a given community the total number of physicians at each age is multiplied by the fraction that expresses their combined service capacity and the results are added, there is provided a comparative estimate of existing local physician resources which is more revealing than a numerical count.

For certain portions of the country and among particular population groups the deficit between physicians in practice—whether considered in terms of a simple enumeration or a calculated capacity to serve—and the number needed for adequate coverage is even more pronounced than when figures are completed on the basis of broad areas. For example, when physician totals are analyzed from the standpoint of community characteristics, one is impressed by the tendency of physicians to locate in areas that present attractions in the form of wealth, physical facilities essential to good medical practice and the presence of other physicians, particularly those representing the specialties. Since wealth seems to be the dominant factor, it will be analyzed first. To simplify the presentation, actual

in a particular area is the presence of general hospitals. Comparative data for physicians and hospitals reveal that large numbers of hospital beds reflect increased physician-population ratios. In those six states providing less than 2 beds per thousand of population there were 1,141 persons for each physician, whereas in the ten states affording 4.5 beds or more there were only 522 persons for each practitioner. While the same basic factor—wealth—influences the location of both physicians and hospitals, data assembled by the United States Public Health Service, but not presented on this occasion, show that the presence of a hospital alone serves to attract and retain physicians.

Factors affecting the physician distribution not only weight the total but to an even greater extent influence the location and migration pattern of the younger men. In 1938, for example, of a group of young practitioners graduated in 1935, 57 per cent remained in large cities and 18 per cent were found in rural areas. In contrast, study of a group of 92,000 physicians long in practice shows that 49 per cent of these established physicians were in large cities and 23 per cent in rural areas at this date. Even when the latter distribution is used as a base—itsself depicting a smaller proportion of physicians than of the general population in rural areas—it is evident that new recruits are particularly inclined to begin initial practice in large cities. Moreover, rural communities not only fail to attract a proportionate supply of recent registrants but also they hold relatively fewer physicians who have developed practices than do urban localities. Analysis of the migration pattern for established practitioners whose period of professional activity extended over a subsequent fifteen year interval reveals that rural areas suffered a net loss of 10 per cent through transfers to more urban communities. On the other hand, physician migration brought about an actual gain of 10 per cent in small cities, whereas in large cities the effect of such changes on physician totals was practically negligible.

The low rate of recruitment combined with the loss through migration has resulted in an age distribution for physicians in rural areas which is heavily weighted in the advanced age categories. As a matter of fact, physicians in rural counties have a median age of 57 in contrast to a median age of 44 for those in large city counties—a difference of 13 years. Since physicians of the rural group are older, the fact that proportionately more physicians are lost from the profession by death in this than in any other location category is not surprising.

This was the picture in 1940. What are the prospects for the future? To begin with, about one third of the active physicians have been withdrawn from civilian practice. Furthermore, despite all efforts to retain physicians where most needed, the number per unit of population is diminishing at an increased rate in states normally deficient in professional resources. Moreover, as a result of the small number of new recruits who have entered practice in the poorer states during recent years, these states have a distribution weighted with older physicians who, because of their age, are subject to a high death rate. For example, in New York State 9 per cent of the physicians were 65 years of age or over in 1940, while in Arkansas and Maine 25 per cent of all practitioners were in that category. Since

Smoothed curves portraying A, relative number of patients seen in a week in 1942 by active physicians of different ages engaged in private practice (number seen at age 40 equals 1.00); B, full utilization of physicians to age 60, declining activity from 60 to 70 and retirement at 70.

physician totals tabulated from the 1940 directory are used henceforth in this paper rather than full service equivalents.

Counties with average annual per capita incomes of less than \$100 attract only 45 physicians per hundred thousand of population. In those with per capita incomes of \$600 or more, the number of physicians for a corresponding unit is nearly four times as great. Among the younger practitioners these differences are sharply accentuated. Of those in practice under 45 there are only 12 per hundred thousand in the counties with the least per capita income, whereas the proportion increases to 92 in the counties of greatest wealth.

Likewise there is a high degree of association between urban character of a county and the number of physicians located therein. Rural, small city and large city counties,⁵ for each hundred thousand of population, average 67, 101 and 179 physicians respectively. That strictly rural counties are at a great disadvantage from the standpoint of availability of medical personnel is strikingly portrayed by these data.

Another factor—itsself an indirect reflection of wealth—which influences the tendency of physicians to settle

5. Rural, small city and large city counties are defined as counties that do not contain any incorporated place of 2,500 or more inhabitants, counties containing cities of between 2,500 and 49,999 inhabitants, and counties containing cities of 50,000 or more persons respectively.

6. The 1942 Census of Hospitals, report of the Council on Medical Education and Hospitals, J. A. M. A. 121: 1699-1694 (March 27) 1942. Exclusive of all mental and tuberculous hospitals, infirmary units of institutions and all other hospitals of federal control except hospitals operated by the Bureau of Indian Affairs.

the general scarcity of physicians renders city locations more attractive, the small number of current graduates who will be channeled into civilian practice will be even less inclined than formerly to engage in rural practice. Thus, states with lowest ratios of physicians and the greatest percentage of loss through death and retirement can expect few accretions to the profession.

The figure suggested as the minimum for wartime safety has already been reached or passed in many areas. Perrott and Davis⁷ have shown that in 1942 there was approximately 1 active private practitioner per thousand persons for the country as a whole. They estimate that early this year this rate will reach 1:1,500. During this year twenty-eight states are expected to have more than 1,500 persons per active private physician. This presents a striking contrast to the six states in a similar position before recruitment for military duty began.

Statistics based on 1940 data show that there was need at that time for relocation of at least 25,000 physicians to bring about a fair measure of equalization in the distribution. Since 1940 the situation obviously has grown worse, owing to the disproportionate loss of physicians from areas formerly deficient. Up to this time there have been practically no replacements.

Because of the present overall dearth of physicians and the widespread augmentation in purchasing power of the American people, urban physicians in civilian practice tend to remain where they are. The relatively few who are now being mustered out of service are, for the most part, older physicians with one form of disability or another. Those with city ties probably will tend to return to their places of residence, while many formerly in rural areas will take advantage of the facility with which city practices can be developed. At present, however, the returning veteran physicians are not sufficiently numerous to make any real impression on the problem.

The great opportunity for mass relocation of physicians will occur after hostilities cease. Already the armed forces contain a large number of physicians who have entered military service directly from hospitals in which they received their intern or residence training. As the war continues, the medical corps will consist more and more of physicians who have never undertaken civilian practice. Moreover, those physicians who engaged in private practice prior to the war soon will have been away for such a period of time that resuming practice will be essentially the same as starting anew.

If, after the war, full advantage is to be taken of the unusual opportunities for equalizing the distribution of physicians, many of the basic difficulties associated with medical practice in underprivileged areas must be overcome. In brief, these difficulties are (1) low income, (2) lack of hospitals and (3) professional isolation. The remedial measures are obvious, though they may not be simple to apply. Matters are further complicated by questions involving both social policy and political expediency.

Combining money assets through a broad program of taxation or insurance would assist materially in solving the economic problem in areas of low per capita income. Another approach would be some degree of subvention for physicians willing to practice in communities where otherwise they could not be assured of a satisfactory financial return. A further requisite for the attraction and stabilization of physicians in rural areas is an

arrangement whereby they will have access to appropriate diagnostic and treatment facilities. The growing interest in rural hospitals must not be taken to imply that every rural physician can or should have a fully equipped hospital immediately at his command. Outposts with diagnostic and first aid equipment must suffice for the more remote areas.

Professional isolation suffered by the physicians in rural communities acts as a deterrent to the establishment of medical practice. Recent medical graduates especially are reluctant to locate in places where, because of restricted professional association, their opportunities for further technical development are limited. With the expansion of hospitals and related facilities, however, it will be easier than heretofore to arrange continuing programs of education for physicians serving in rural areas. An additional measure for promoting professional growth is the provision of periodic refresher courses. To this end pilot projects undertaken by certain of the universities and medical societies should be extended, systematized and given a stable basis of financial support.

Another way in which a substantial impression might be made on rural medical practice is that of bringing about more effective utilization of physicians who do elect to practice in those areas. Solution of this question, while applicable to all physicians, is more urgent for those in the less populous regions. Excessive wastage of time and strain imposed by travel, together with responsibility for both day and night calls, taxes to the utmost the physical capacity of the practitioner serving rural communities. In the chart indicating the proportion of patients seen at each age level, curve B is constructed to show the extent to which the effectiveness of physicians at both ends of the age scale might be augmented. Studies⁸ show that if maximum use could be made of the professional capacity of physicians at all ages up to 70 years the total volume of physician service available to the general population might be increased by about one fourth. Such a purpose is not likely to be attained unless physicians work as groups, preferably in connection with hospitals or health centers. In this manner both the potential capacity of the younger man can be utilized and the energy of the more experienced physician conserved. Experienced practitioners could then devote much of their time to consultation. By this procedure the younger physician receives seasoned judgment, the older man is relieved of much time and energy consuming detail, and, what is more essential, the patient benefits by the team work.

SUMMARY

Low income, lack of essential facilities and professional isolation contribute to the maldistribution of physicians. If, after the war, full advantage is to be taken of the unusual opportunities for equalizing the distribution, many basic difficulties associated with medical practice in underprivileged areas must be overcome. Combining money assets through a broad program of taxation or insurance would assist materially in solving the economic problem in areas of low per capita income. Arrangements should also be worked out whereby physicians in rural locations will have access to appropriate facilities—either hospitals or health centers. In addition, provision for periodic refresher courses should be an integral part of any scheme for improving and extending medical practice.

PRIMARY CARCINOMA OF THE TRACHEA

TREATMENT WITH INTRATRACHEAL RADIUM; RADIOACTIVE IODINE FAILS TO SHOW THYROID ORIGIN

PHILIP H. PIERSON, M.D.

SAN FRANCISCO

Carcinoma of the trachea was apparently first recognized by Türck¹ in 1866, at which time he described 2 cases in which the disease was secondary to carcinoma in the esophagus and 1 case in which it was secondary to carcinoma of the thyroid. The first case of primary carcinoma of the trachea was reported by Langhans² in 1871. His patient, a man of 40, had suffered from dyspnea for a year and finally died of suffocation. It was found that "his primary disease had originated in the submucous glands and eventually involved not only the trachea but some spread had occurred into the right stem bronchus."

A review of the literature will be made later.

The patient who is the subject of this report is well after two years and presents several problems that are interesting and instructive:

REPORT OF CASE

R. H., a man aged 61, married, a lecturer, whose past history was irrelevant, had a great deal of cough and was very tired during the last six months of 1938. There was no shortness of breath, wheezing or loss of weight. He was quite comfortable during the first six months of 1939, but during the summer his cough returned and he expectorated some blood on several occasions during August and September. By November he was again feeling very tired (possibly because of a very heavy schedule). Every two or three months after November 1939 he had bouts of cough and sputum, which was frequently bloody, but there was no fever. During the later part of 1940, while at an altitude of 4,500 feet for two months, he noticed more shortness of breath than for a long time. Because of the protracted "colds," cough and hemoptyses, he came to Palo Alto, Calif., in December 1940. The cough was somewhat better, but periodically there were bouts of hard coughing, expectoration of some yellow material and somewhat larger quantities of blood. It was not until March of 1941 that he developed wheezing, which not only interfered with his lecturing but reduced his voice to a whisper. This was associated with periods of intense suffocation. He had never seen a doctor about it before 1941. In May, after nearly three years of symptoms, he consulted Dr. Russell Lee, who referred him to me. His weight had fallen to 147 pounds (67 Kg.) from a customary 160 to 165 (73 to 75 Kg.). His father and brother had died of cancer of the lung, and several of the family had had tuberculosis.

Physical examination was negative except for enlarged tonsils and a slightly prolonged expiration at the base of both lungs. X-ray examination of his lungs showed some increased linear markings at both bases but a normal mediastinum. On May 24 bronchoscopy revealed a tumor (fig. 1) just above the carina, occupying at least one half of the lumen of the trachea. It extended over the whole cartilaginous portion of the lower trachea for a distance of 2.5 cm. but apparently spared the posterior portion. Its base was broad and firmer than the pale, lobulated and softer superficial tissue. Biopsies were taken then and at subsequent operations and have been summarized

From the Department of Medicine, Stanford University School of Medicine.

Dr. Robert E. Newell of the Department of Roentgenology devised the radium carrier and supervised its application. He also gave help and encouragement throughout. Dr. David A. Wood of the Department of Pathology gave untiring cooperation. My son, Dr. Robert E. Pierson, made the drawing.

1. Türck, L.: Klinik der Krankheiten des Kehlkopfes und der Luftröhre, Vienna, W. Braumüller, 1866.

2. Langhans: Primärer Krebs der Trachea und Bronchien, Virchows Arch. f. path. Anat. 53: 470, 1871.

by Dr. David Wood as follows: "The tumor is a low grade, well differentiated primary carcinoma of the trachea. This tumor could well have had its origin from submucosal tracheal glands. Its acinar structure and intra-acinar homogeneous secretion, however, cause the tumor to bear a striking resemblance to neoplastic thyroid tissue. Histogenically its possible origin from aberrant thyroid tissue cannot be definitely excluded. Inability of the tumor to store radioactive iodine does not exclude its possible origin from aberrant thyroid tissue. The possibility of the tumor being metastatic from thyroid tissue elsewhere is extremely remote. Therefore the case at the present time is considered to be one of primary adenocarcinoma of the trachea."

After the second bronchoscopy the patient felt a great relief in his breathing and after five sessions of removing as much tumor as possible its appearance on October 23 was that of a very superficial layer of tumor tissue.

The question arose as to whether this tumor developed from a misplaced anlage of thyroid tissue, although roentgenograms showed no substernal mass suggesting a thyroid gland and

Fig. 1.—Bronchoscopic appearance of tumor.

Fig. 2.—Radium applicator completely folded in the bronchoscope.

laminograms also quite accurately delineated its size and position. We hoped to determine this by use of radioactive iodine, which Dr. Joseph Hamilton of the Radiation Laboratory at the University of California provided. The patient drank a small portion of the material on September 22 and when tested with the Geiger counter September 24 showed intense activity (several hundred counts per minute) in the lower part of the neck. Development of a "cold" prevented bronchoscopy, however.

On October 21 the counter, set close before the neck, gave only 50 counts per minute ($4\frac{1}{2}$ times the background). He then drank another dose (200 microcuries) of radioactive iodine, with immediate increase in the general body radioactivity (counts close to the hand, 30 per minute). On this occasion the concentration in the neck was not followed. Two days later, October 23, I removed several pieces of tumor by means of the bronchoscope. Dr. Hamilton examined these but could find no radioactivity in them. This ruled out the presence of normal thyroid tissue but did not necessarily exclude carcinoma of the thyroid, for malignant thyroid carcinoma is known not to collect radioactive iodine as normal or hyperplastic thyroid does.

At this bronchoscopy I had planned to treat him with radium in a special applicator which Dr. Robert Newell had prepared, but this was broken during the attempt to place it. Dr. Newell

rebuilt the radium carrier, and on November 6 I placed it in the trachea in the region of the residual tumor. X-ray films were made with the tip of the forceps held at the distal margin of the tumor and the bronchoscope held at the proximal border; then the placement of the radium was checked with films according to these. The patient coughed the radium out after three and one-half hours.

Fig. 3.—Radium applicator partly protruding from the bronchoscope.

On November 27 radium was placed similarly, but the applicator was broken against the bronchoscope in trying to readjust its placement; it was retained for about one-half hour. On December 19, by means of a new applicator, radium was placed again, everything going smoothly because the patient was well sedated, and was successfully retained for five hours, as planned.

The radium was in four tubes, each containing 25 mg., set with 12, 16 and 12 mm. spacings down the axis of the trachea. Allowing for crossfire, the calculated total dosage November 6 to December 19 amounted to about 5,000 roentgens at a radial distance of 8 mm. and about one-half that at a radial distance of 12 mm.

Since treatment the patient's tracheal condition has been studied in April 1942 and in January and November 1943, and at all of these times there has been no evidence of any abnormality except possibly a little thinning of the mucous membrane in the area occupied by the tumor. On physical and x-ray examination there was no evidence of any increase in the mediastinal glands. The patient's general health is excellent; he walks considerable distances and lectures without any shortness of breath or cough. He shortly regained his normal weight and has maintained it.

Fig. 4.—To show size of applicator.

SUMMARY

A man of 61 who had intermittent bouts of severe cough, dyspnea, suffocation and moderate hemoptyses for three years was found to have a primary adenocarcinoma of the trachea. An attempt to prove the histogenic origin from aberrant thyroid by the use of radioactive iodine was unsuccessful. After removal of as much as possible of the tumor through the bronchoscope, the remnant was treated by radium applied within the trachea. Two years after treatment there are no subjective or objective evidences of tumor.

COMMENT

In 1890, reported in 1898, von Bruns³ operated on a patient aged 31 in whom dyspnea had been present for ten years. The tumor he found apparently had arisen from thyroid tissue. It was his feeling "that thyroid tissue might be present in the trachea (1) from aberrant thyroid tissue in the germ or (2) that it could penetrate from outside into the trachea between the tracheal rings during extrauterine life. This can happen only if there is a growing together of the thyroid gland and trachea, established by an embryological disorder of development of the thyroid capsule which is missing there, allowing the glandular tissue to proceed directly into the perichondrium." His operation removed the trachea over a distance of ten rings and also the anterior surface of the esophagus. A tracheal tube was put in place and the patient was comfortable until stenosis again occurred and he died, six years after the first operation. This is apparently the first operation for the complete removal of a primary carcinoma

Fig. 5.—Radium applicator in trachea, bronchoscope being withdrawn.

of the trachea. He also felt that in two thirds of the reported cases the tumor was in the upper and middle thirds of the trachea and that very rarely did a carcinoma there metastasize or invade the surrounding tissues.

In 1908 Nager⁴ reported that in observations made at the Pathological Institute at Basel, Switzerland, between 1871 and 1905 in 1,078 cases of carcinoma the thirteenth in frequency were 19 cases of carcinoma of the lungs and bronchi and twenty-second were 9 cases of carcinoma of the larynx, and no cases involving the trachea were found. He reported a case in which a squamous cell carcinoma measuring 3 by 3.5 by 2 cm. was present just above the right main bronchus, and he states that this location near the bifurcation is favored for tumors and diverticula because this is the region where the separation of the "anlage" of the lungs and the foregut starts.

3. von Bruns, P.: Resektion der Trachea bei primärem Trachealkrebs, Beitr. z. klin. Chir. 21: 284, 1898.

4. Nager, F. R.: Ueber das primäre Tracheal Carcinoma, Arch. f. Laryng. 20: 275, 1908.

In 1909 Schmigelow,⁵ reviewing the literature, found that von Bruns had collected 28 cases of primary carcinoma of the trachea, and he added 12 more from the literature and a case of his own, in which he had done a tracheal resection, the patient being well six years after the operation.

In 1911 Simmel⁶ reported the occurrence of difficulty in swallowing, cough, fetid expectoration, hoarseness (paresis of both vocal cords), hemoptysis and cachexia in a man aged 77. Esophageal "probing" located a resistance 25 cm. from the teeth, and this was thought to be due to a carcinoma of the esophagus perforating into the trachea. At postmortem a primary carcinoma of the trachea was found, with the esophageal lining intact, the tumor extending from just below the cricoid cartilage to a few centimeters above the bifurcation, producing a diverticulum of the trachea.

By 1913 von Bruns⁷ brought the number of reported cases of primary carcinoma of the trachea up to 81 and an additional 174 cases of benign tumors of the trachea, making the ratio of malignant to benign tumors of the trachea about 1:2. To this figure of 81 Heymann⁸ added 33 cases from the literature and 1 of his own. After two attempts to remove the tumor completely by tracheoscopy had failed, transverse resection of the trachea was performed by Gluck and the patient was well two years later.

In 1915 Soerensen⁹ reported another case of "aberrant retrotracheal goiter showing cancerous degeneration and growth into the trachea from behind." The patient was well two years after transverse resection of the trachea. He strongly recommended resection of the trachea because (1) other methods of operation were insufficient, (2) it was relatively not dangerous, even in total removals, and (3) the functional effects were good if the recurrent nerve could be preserved. He felt that it was contraindicated if the bifurcation itself was involved by the tumor or if the vessels in the neck were grown together. Growing together of the esophagus and trachea would not exclude, *ipso facto*, the possibility of operation.

According to Chiari,¹⁰ primary carcinomas are the most frequent tumors of the trachea and occur more often in men between the ages of 50 and 60. They generally form broadly sessile tumors with globular or knobby surfaces, sometimes extending over several rings, but seldom are they pedunculated, and rarely do they infiltrate deeply below the surface, at least not until a considerable time has elapsed. They may eventually extend into the mediastinum, esophagus or thyroid gland. Secondary carcinoma may develop from cancer in the larynx, or it may be from the esophagus, bronchus or thyroid. Very rarely is it metastatic in the trachea from any distant focus. He too feels that radical intratracheal extirpation is rarely successful and that the operation of choice is radical transverse resection of the trachea.

Feichtinger¹¹ proceeded with his operation in two stages: first a tracheotomy for full exploration of the extent of the tumor and later transverse resection.

Otto Maier¹² removed a papillary cystadenoma in his case by a deep tracheotomy and then extirpation of the tumor by "bisecting the trachea downward," suturing its walls together after the removal of the tumor.

The largest group observed by one person up to 1921 was by Fraenkel,¹³ who carefully studied 8 cases. His conclusions were, briefly, that it is a rare condition, found more often in men than in women and between the ages of 50 and 70. Its location is generally at or near the bifurcation, having a preference for the anterior and not for the posterior wall, as previously stated, and its shape is that of a flat infiltration rather than of a globular tumor. The general symptoms, although not pathognomonic, are hoarseness or a debility of the voice, cough with uncharacteristic sputum, dyspnea of varying degrees, stridor and often trouble with swallowing. He places some importance on the early beginning cachexia, the swelling of the glands in the neck and bouts of suffocation. The diagnosis is made by roentgenograms and tracheoscopy with biopsy. The course of the disease varies from three months to two years. In his experience death results from the extension of the disease into the surrounding tissues. He feels that the origin of the tumors is chiefly from the epithelium of the mucous glands and only rarely from the pavement epithelium.

Stenström¹⁴ apparently agrees with Fraenkel in regard to the extension of the tumor to the mediastinum, for in 13 of 19 cases it had infiltrated the mediastinum, and only 6 were completely confined to the trachea.

Between 1925 and 1933 a few cases were reported by Borries,¹⁵ Soerensen,¹⁶ Hart and Maycr,¹⁷ Holmgren,¹⁸ Minnigerode,¹⁹ Wolfgang Tiling²⁰ and Teubner.²¹ The extreme rarity of the disease is statistically presented by Holmgren and Wolfgang Tiling.

In 1926 Adam²² reported 4 cases of tracheal tumor, 2 epitheliomas, 1 soft fibroma and 1 endothelioma. He treated the first 2 with radium, but death occurred within six months.

The patient observed by Bowing and Vinson²³ had been ill three and one-half years with frequent colds, hemoptyses, slight fever, cough, considerable dyspnea on slight exertion and frequent asthmatic seizures. He had been sent to New Mexico for tuberculosis. They found a tracheal carcinoma, removed it by surgical diathermy and gave radium over the sternum.

A few other cases have been reported in the American literature, but their repetition adds little more to what has been already described.

SUMMARY

The American and foreign literature disclose the fact that primary carcinoma of the trachea is a very uncommon disease. With increasing use of endoscopy its presence may be recognized more frequently. Operative procedures, such as removal of a portion of the trachea, have been carried out with varying success. Endoscopic removal of the tumor with x-rays and radium have also been used, but the results have been disappointing.

In the case reported as much as possible of the primary adenocarcinoma of the trachea was removed endoscopically and then intratracheal radium was applied.

Radioactive iodine was used to determine whether any normal or hyperplastic thyroid tissue was present in the tumor.

The patient is well, subjectively and objectively, two years after treatment.

490 Post Street.

THE DERMATOLOGIC ASPECTS OF THE
VESICANT WAR GASES

MAJOR MARION I. JEFF DAVIS

MEDICAL CORPS, ARMY OF THE UNITED STATES

Of 27,111 hospital admissions due to use of poisonous mustard gas during World War I, 30 per cent showed involvement of the skin. This figure is significant and indicates to us, as dermatologists, the necessity of a greater familiarity with this relatively unknown field of war medicine.

Lewisite, one of the arsenical group of gases, is another type of vesicant agent that has been developed since the close of the last war. This discussion will consider experimentation and clinical observations that I have made on the mode of action of these two gases, mustard and lewisite, on human subjects.

MUSTARD GAS

Mustard gas is an aliphatic sulfur compound which in the pure state is a colorless, odorless, moderately volatile liquid whose density is 5.5 times that of air, having a boiling point of 217 C. and a freezing point of 14 C. The plant product, whose formula is bis-beta dichlorodiethyl sulfide ($\text{Cl} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{S} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{Cl}$), is used on the field. This is a thick dark brown to black oil characterized by a pungent garlic odor. Owing to its low vapor pressure it may form a persistent heavy mist that remains in the atmosphere for a considerable period after discharge. It is sparingly soluble in water but soluble in organic solvents and organic fats. Oilskin, rubber and cellophane offer some resistance to this synthetic product; ordinary dry clothing and leather afford slight protection, and wet apparel practically none.

Mustard gas acts on the respiratory system and the eyes unless a man is masked; then its chief action is on the skin. There is no pain or irritation on immediate contact with the skin. In a vapor exposure, absorption takes place coincident with the exposure of the skin to the vapors. No mustard gas remains on the skin surface after the exposure is over. In a liquid contamination only a small portion of the mustard gas is

absorbed by the skin, as the vast majority of the gas evaporates into the air unless it is removed by other means.

This agent enters the cuticle presumably by absorption through the epidermis and by penetration of the glandular orifices and hair follicles of the skin surface. The rate and degree of penetration are influenced by such factors as local keratinization, epidermal thickness, supply of gland appendages and variations in the amounts of sweat and sebum present on the glabrous skin. Complete and irreparable damage of cellular tissue takes place within ten to fifteen minutes after liquid contamination of the skin. Most of the mustard gas becomes fixed in the epidermis, while the remainder which is free is transmitted, via the circulation, to various organs of the body.

The exact mechanism involved in the production of vesication and burn by mustard gas is not definitely established. It is the general consensus that the effects of mustard gas are due to a combination of the entire mustard gas molecule with cellular tissue. Precisely what substance or substances of skin the mustard gas combines with is as yet undetermined. However, it is believed to be some protoplasmic protein vital to cell life, perhaps a portion of one of the enzymatic systems.

Mustard gas is insidious in its action. Both the liquid and the vapor are nonirritating to the skin and give no warning. Disabling concentrations of mustard gas vapor may have so little odor that one is not aware of the danger. Likewise, liquid contaminations of the skin or clothing may go unnoticed.

There is a latent period between the time of exposure and the onset of signs and symptoms. This period varies from several hours to several days. Generally, the greater the degree of contamination, the shorter will be the latent period and the greater will be the injury produced. Early skin changes are often preceded or accompanied by nausea or vomiting coupled with a feeling of general exhaustion. In severe exposures these symptoms appear within two or three hours after the initial exposure.

In mild vapor exposures and small liquid splashes, only the exposed skin surfaces are affected. In extensive liquid splashes or more severe vapor exposures there is permeation and penetration of the clothing with the general involvement of the covered portions of the skin. Warm, moist areas of the body are the sites of predilection for mustard vapors: face, neck, axillae, antecubital fossae, groin, genitalia and perineum.

The earliest change in the skin is an erythematous blush often appearing first on the neck, shoulders, arms and legs. Within a few hours there is a generalized bright erythema. The patient presents the appearance of severe sunburn. Bands of normal white skin, which have been protected by thick shoulder straps of an undershirt or the cross belt of a gas mask, streak through these areas of bright erythema.

The appearance of the erythema may be the patient's first indication that he has been burned. There is mild pruritus and prickling of the skin at this time, which increases in severity as the erythema reaches its height. Discomfort becomes more pronounced in the flexural surfaces over the antecubital fossae, neck and popliteal spaces. The skin feels hot and the body temperature may rise to 100 to 102 F.

A generalized brawny edema develops early in this erythematous stage, which is accentuated in severe cases. It may be a superficial edema involving the epidermis or a deep pitting subcutaneous edema. On the extremi-

Major Davis is chief of the Dermatology and Syphilology Section, Cushing General Hospital, Framingham, Mass.
Read before the Section on Dermatology and Syphilology at the Ninety Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

ties, evidence of edema may remain long after the skin itself has returned to normal. The penial and scrotal lesions are often the most severe part of the skin involvement. The scrotum may become the size of a large grapefruit.

Within six to twelve hours, groups of multiple pinpoint vesicles appear. These vesicles soon coalesce to form blebs and bullae of varying size. At times the vesication resembles "crape rubber" or it may assume a ring shape like that of a doughnut.

There is progressive involvement of the skin during the first six to eight days. Pain and discomfort likewise increase in intensity. Sleep is difficult to obtain for the patient despite massive doses of sedatives. By the end of the first week the erythema, vesication and general discomfort reach their peak and begin to subside. Many portions of the skin become raw and denuded. There is weeping, oozing and maceration of some areas followed by fissuring, cracking and superficial ulceration with subsequent crusting. This is particularly true of the flexural surfaces and the genitalia. Eventually the skin becomes dry and parched and assumes a brownish to purplish hue. This deepening of pigmentation continues for a number of days. Desquamation then ensues and continues over a prolonged period. Many portions of the dry epithelium come off in strips and casts much as it does in scarlet fever.

Where liquid mustard gas comes in direct contact with the skin a typical blister develops. The bulla is superficial, round to oval with a thin, translucent, tense roof, and has a glistening golden yellow appearance. Vesication takes place in the center of an erythematous base, so that there is a halo of erythema surrounding the fully developed bulla. There is a wide area of surrounding edema, its extent depending on the degree of burn. The involved area is many times the site of original contamination. In large liquid contaminations the doughnut type of bulla develops. Here one sees a central dull, dirty white area of superficial necrosis surrounded by a ring of vesicle formation of varying width. Here the reaction between mustard gas and the cellular tissue has been so rapid and immediately necrotizing as to prevent the intervening stage of vesicle formation. The vesicle fluid is golden yellow and freely flowing when the early bulla is incised. Later the fluid becomes gelatinous and cannot be aspirated with a large gage needle. The base of the exposed bulla is moist and hemorrhagic. The fluid of an intact bulla or vesicle is reabsorbed within a week.

Lesions, uncomplicated by infection, heal without scar formation. There is characteristically a residual pigmentation due to a melanoblastic stimulation of the basal cells, which requires a number of weeks for resolution. The average case requires a month's hospitalization, the more severe cases several months'.

LEWISITE

Lewisite, a nonmetallic alkyl derivative, was synthesized by the late Dr. Lee Lewis at the American University near the close of the last war.

This gas is as yet untried on the battlefield. The Germans employed ethyldichlorarsine, a similar but less effective arsenical vesicant, during World War I.

Lewisite (beta-chlorovinyl-dichlorarsine) is representative of a group of trivalent arsenical compounds whose vesicant action and highly toxic nature are of prime importance. In its pure state it is a colorless, highly refractive, volatile liquid with no odor. However, it is extremely irritating to the nasal mucosa.

giving rise to coryza, accompanied by sneezing and lacrimation. The impure form used in the field is brownish black with the odor of geraniums. Lewisite boils at 190 C. and freezes at -18 C. It is soluble in organic solvents and sparingly soluble in water. Hydrolysis by water or alkalis yields the corresponding hydroxide or oxide. The latter is one tenth as vesicant as lewisite and nontoxic when applied to the skin.

Liquid lewisite absorbed from the bare skin is capable of producing acute arsenical poisoning and death. From animal experiments it appears that 1 cc. of liquid lewisite absorbed from the skin would be fatal to man. Lewisite combines with certain chemical constituents within the cell. This reaction is reversible during the first few minutes but later becomes an irreversible reaction.

High concentrations of lewisite vapor produce mild vesication. Although lewisite vapor is less effective than that of mustard gas, liquid lewisite causes a more rapid, severe and deeper burn than liquid mustard gas. In contrast to the absence of any symptoms on contact of mustard gas with the skin, lewisite (liquid) produces an almost immediate stinging and burning sensation (ten to twelve seconds).

During the first fifteen to twenty minutes a dull dead white or grayish area appears at the site of contamination. Within several hours the involved site increases in size and there appears an urticaria-like wheal, with central lemon colored area surrounded by a peripheral erythema. This center later becomes blanched in color, with the skin orifices puckering to give the appearance of tanned pigskin. Within six to eight hours pinpoint areas of vesication appear. These gradually coalesce to form a bulla, which covers the entire area of erythema so that early in its formation the underlying erythema sometimes reflects through the bullous roof to give the effect of an iris-like bullous lesion. The peripheral erythema and edema that are characteristic of the mustard gas blister is lacking in the early lewisite burn but appears later. The base of the exposed lesion is exudative, hemorrhagic and raised above the level of the surrounding skin. There is a sharp demarcation between skin involved by the burn and the normal skin, in contrast to the mustard gas burn, in which there is a variable amount of involvement of the adjacent skin.

The lewisite bulla tends to be more opaque and more cloudy than that of mustard gas and may be more flaccid. The vesicle fluid was until recently considered vesicant and to contain sufficient amounts of arsenic to be toxic. I have been able to show both by quantitative chemical analyses and by clinical experiments that the fluid is nonirritant, nonvesicant and nontoxic. In these same experiments it was shown that the vesicle fluid contained only infinitesimal amounts of arsenic (0.001 to 0.002 mg. per cubic centimeter of fluid).

Resolution and healing of a lewisite blister take place in much the same fashion as that of the mustard gas blister. It has been thought by some observers to heal more rapidly than mustard gas burns, but I cannot assent to this opinion. Residual pigmentation in small lewisite burns is not as characteristic as in mustard gas but is often seen to occur in large burns. The lewisite lesion leaves a residual atrophic scar in healing more often than does mustard gas.

PATHOLOGY

A number of factors influence the physiologic action of the vesicants, such as the physical properties of the agent, as well as the concentration and duration of

exposure. The influence of climatic factors on the physiologic action and general cellular activity of the skin are clearly demonstrated in the instance of the vesicant agents. The entire reaction between cellular tissue and the agent is much accelerated by elevations of temperature and humidity. Doses of the vesicants which in the winter produce only a mild erythema result in the hot summer in a burn requiring several weeks to heal.

In the biopsies of mustard gas burns that I have studied the pathologic changes are practically confined to the epidermis. There is a vacuolar or hydropic disintegration of the cells with eventual rupture of the cell membrane. Spaces formed by the progressive liquefaction and disintegration of these cells becomes filled with fluid exudate to produce an intradermal vesicle. The base of this vesicle, which rests on the surface of the corium, presents an occasional remaining basal cell. The roof of the vesicle consists of an upper layer of epidermal cells that remain viable for a time and a lower layer of necrotic or disintegrating cells.

The vesicle contains a homogeneous or fibrillar eosinophilic staining fluid in which there are a few polymorphonuclear leukocytes. Some of the hair follicles appear necrotic for a short distance from the surface, but there are no significant changes of the sebaceous glands, sweat ducts or sweat glands. There is some edema of the superficial corium with capillary dilatation and perivascular edema and mild perivascular infiltration of lymphocytes and polymorphonuclear cells.

In lewisite there is an early complete necrosis of the entire epidermis. This necrotic process extends into the corium, where there is manifest vascular damage and polymorphonuclear infiltration. Vesicle formation is intradermal as in mustard gas lesions, but beneath the vesicle roof there is attached the entire thickness of the necrotic epidermal layer. The pathologic changes in the lewisite lesion are in contrast to the slowly progressive hydropic disintegration confined to the epidermal layer that is seen in mustard gas lesions.

Vesicant burns, while in many respects analogous to those produced by heat and chemicals, offer certain contrasting features. The vesicants do not produce the immediate coagulation necrosis that occurs with thermal, electric and other chemical burns. Again only minute amounts of the agent are necessary to produce severe cellular destruction. Latency, recrudescence and a delayed period of development are peculiar to vesicant burns. With mild contamination, especially of mustard gas vapor, the skin may show no evidence of burn for as long as two to six days after the original contamination when erythema appears. This is an extreme example of the latent period. A vesicant lesion which appears to be properly healing under treatment may show a flare of reactivity ten to fourteen days after the original burn has been inflicted. Such a recrudescence of the burn is usually a papulorhythematous type of eczematous dermatitis occurring about the periphery of the healing burn, which may or may not be associated with vesiculation. Vesicant burns, especially when large portions of the skin are involved, often do not show their maximum involvement for a period of one to several days or more after the patient has presented himself for treatment. Areas of skin which twenty-four hours after the original contamination still appear normal may at a later date become involved, and lesions already present may increase in severity. This clinical observation of the delayed development of vesicant burns is substantiated by pathologic find-

ings. Microscopically there is a prolonged period involved in the development of complete cellular necrosis.

Vesicles have been observed to occur in the old healed scar of vesicant lesions weeks to months after the burn has entirely healed. This phenomenon, at least in my experience, does not occur in thermal burns.

Sensitivity tests performed with very high mustard gas dilutions show the light complexioned to react to a greater degree than the dark skinned or colored individual. However, with sufficiently large exposures these differences disappear. Repeated exposure or burn with mustard gas is capable of producing sensitization to the agent. In a person who has developed this sensitization, an amount of mustard gas sufficient to produce a small burn on the normal skin will result in a very large burn on the sensitive skin. This phenomenon of sensitization from repeated exposures to mustard gas has also been demonstrated by experiments on the pig's skin.

True allergic states have been observed in persons working with mustard gas. In these individuals a fresh mustard gas burn on a previously unburned site of the skin will produce a vesicular reaction at a distant healed site of a mustard gas burn received years previously. These people will also respond to a generalized vapor exposure in a similar fashion. Allergic reactions due to lewisite have been known to occur but are rare.

There is danger of arsenical poisoning from the absorption of lewisite following severe burns, while small mustard gas burns are free from accompanying toxic manifestations. With large areas of skin involved in mustard gas burns, however, there develops a generalized toxemia, hemoconcentration and the other associated signs of shock.

TREATMENT

The emergency prophylactic treatment of vesicant contaminations is the responsibility of the individual soldier. The physician is chiefly concerned with treatment of the burn.

In severe cases the treatment of shock and toxemia is of primary importance. In the mild erythematovesicular cases treatment is the same as that for any acute generalized erythema, i. e. bland lotions and ointments, baths, sedation and so on.

The definitive treatment of vesicant burns differs but little from that usually employed for thermal burns. One may choose almost any of the generally accepted technics of burn treatment which one may prefer.

It has been my experience as well as the experience of others working in this field that the healing time of vesicant lesions is not greatly influenced by the type of therapeutic agent employed except for a few notable exceptions. I have employed ten day occlusive dressings on a large number of burns with a resulting increase of ten days in the healing time as compared with open dressings regardless of the therapeutic agent used in either instance.

The healing time of blisters which were incised and drained was compared with the healing time in blisters which were left intact. There was no difference found in the healing time. However, drainage of the vesicle fluid does give relief to the patient. Amyl salicylate, which in common with other salicylates possesses analgesic properties, has been recommended during the first five or six days of treatment. This is a saturated solution used in the form of a wet dressing. I have employed it in experimental burns of 3 inches diameter.

I have found it to have some analgesic effect in the acute stage, but it does not shorten healing time. Sulfanilamide crystalline powder and sulfonamide ointments appear to have no advantage over a boric acid ointment dressing in the small localized lesions. Workers are in general agreement that escharotics give poor results in vesicant lesions.

There is one major difference between vesicant and thermal burns which must be kept in mind, and that is the delayed period required for the full development of the vesicant lesion. Therapeutic measures and clinical prognosis must in some instances be guided by this fact.

ABSTRACT OF DISCUSSION

COMMANDER ROBERT L. GILMAN (MC), U.S.N.R.: If war gases are never utilized in the present war it will be due in no inconsiderable measure to the Chemical Warfare and allied services, which, in association with civilians and service physicians, have worked so thoroughly on antigas defense, as well as shared in the development of these modern implements of offense. There are certain features in the action of vesicant gases, as pointed out by Major Davis, such as the short but definite period between exposure and the beginning of skin irritation, and the latency or refractory period (in mustard gas) before symptoms appear that dictate to a large extent the measures used in prophylaxis, decontamination and treatment. The clinical and histologic observations of the author and others have been instrumental in outlining rational therapeutic procedures. An additional consideration is concerned with lewisite, and that is that its severity of reaction is due largely more to the contact with the skin of minute liquid droplets than actual gaseous vaporization. This difference in contact and the arsenical content make this gas capable of more severe skin burns as well as toxic systemic effects. We have certain protective devices and prophylactic measures and they are all designed to put an impenetrable curtain between the gas and the man or material. These include protective clothing, ointments and covering material. The latter are protective only in a relative manner. Once material or equipment has been contaminated, considerable effort must ensue if complete salvage is to be obtained. Prophylaxis merges directly into decontamination, which in turn is the first step in treatment. Solvents and soap and water have been mentioned. Action must take place promptly and oftentimes with only the means at hand, such as a thorough dousing or flushing with sea water. The treatment and management in this war will follow proportionally our advantages gained since the last war in the treatment of shock, fluid loss, severe dermatitis and burns. These constitute the major effects of the vesicants, and in the last war these "burn cases" (as they were termed) were treated similarly to any other type of burn casualty. Men were cradled under heat lamps, their beds screened with mosquito netting, while a variety of applications were used locally, ranging from bland ointments to antiseptics, and the use of a variety of "burn specifics." The moderately burned did well, while the severely burned often died of concurrent pneumonia, sepsis or shock. I believe that any future vesicant gas casualties will be treated exactly as we do those of shock or thermal burns at present.

DR. CHARLES C. DENNIE, Kansas City, Mo.: I was a mustard gas officer in the last war. We saw hundreds of cases of mustard gas burns of all degrees of severity. The thing that impressed me most was the fact that these men did not die from mustard gas—only a small percentage of them. Of course, it took them from twenty-four to seventy-two hours to arrive at our hospital, and the ones who were going to die probably died before that time. They manifested all degrees of burns, and about 10 per cent of the total number of casualties were severe burns. The thing that struck me most forcibly was the gelatinous material that was secreted beneath the giant vesicles. Some of these were blebs; some were as much as a foot long and 8 inches wide and would cover both thighs and the buttocks. Most of the casualties occurred during July and August, when the weather was hot and when there was dense

humidity in the air. A great many of these men wore defective gas masks and they got an interstitial keratitis, which took much longer to cure than an original gas burn. They had all the manifestations of interstitial keratitis of syphilitic origin, including photophobia. They also, when they had defective gas masks, developed a severe burn of the upper respiratory tract in such a manner that they coughed up membranes a great deal like diphtheritic membranes, and in a few cases diphtheria was a complication. In treatment, we used only transfusions in those days; such a thing as using serum or plasma was unknown. Yet these men whom I saw, 12 of them in that first group of cases, lost much plasma but did not die from plasma loss. With the large vesicles we could take the gloved hand and throw the plasma off on the ground. In those cases the plasma had to be removed. We didn't know what to do with them, so we washed them with salt water and then we found after a little experimentation that the thing that gave the most ease was 2 per cent sodium bicarbonate in petrolatum.

DR. LEON GOLDMAN, Cincinnati: The remarks of some one who has had practical experience in this field are a lot more important than those of us who work in the experimental laboratory or had just a lot of library experience. One of the points that Major Davis brought up in his paper was the fact that a molecular intact mustard agent can be isolated from the lower layers of the skin and also found in the blood vessels away from the skin lesion. This is rather important for us who work in civilian dermatology because the principles of the study of these penetrating, persistent, equally strong irritant and sensitizing agents can be carried over into experimental work in civilian dermatology. With what he has told us about mustard gas and with the remarks of Dr. Cowdry a few days ago on the dynamic morphologic anatomy of the skin, we can really find out the fate of many of our contact agents in the skin. I should like to ask Major Davis if he has had any experience with cross sensitization between mustard gas and the less irritant but much more dangerous systemic agents, the so-called nitrogen mustards. From my work I can substantiate the findings of Major Davis and also of Sulzberger and Katz that the lewisite blister fluid is not irritant to the skin and also the roof over the lewisite blister is certainly not dangerous to the skin and contains little, if any, arsenic. I am curious to know what happens to 30 plus arsenic which has been deposited in the skin from lewisite agent. I have tried to find it by sulfide staining technics and am certainly not satisfied. Another point is the observation of Major Davis about the late appearance of vesicles in old scars, which I do not believe has been noted before in contact dermatitis. I have seen this phenomenon in old burns, especially in old stasis scars and in postoperative breast amputation scars, but there I have assumed that these fluid collections were due to mechanical trauma. I wonder if Major Davis can say anything about the value of protective ointments in the immediate emergency. All of us are concerned about whether there are such things as true protective ointments, as for instance in industrial dermatology. I should like to ask Major Davis too if he can say something of his important work in the field of antiarsenical agents as related to lewisite poisoning, since many dermatologists are concerned with arsenical reactions.

DR. C. GUY LANE, Boston: I have seen a few research workers with mustard gas and a few who are developing gas proof fabrics. One of these workers showed an interesting feature. She was working in front of a hood, where the fan was not turned on. The manager of the plant was beside her and another worker on the other side of her. She was handling some mustard gas just in front of her. She came to me about a week later with a mustard gas burn on the lower part of the abdomen, involving the pubic region and inner thighs, which was quite disturbing for several weeks. Curiously enough, on the lower part of the abdomen it was easy to see the markings of her girdle, where the gas had apparently penetrated. She was perfectly unconscious of anything going on at the time. It is important for workers to follow absolutely directions about protection. It is also important for them not to use too strong a solution to neutralize the mustard gas. There were several cases in a group that thought that because the routine strength of the neutralizing agent was good a stronger solution would

be much better. Their manifestations did not suggest mustard gas and disappeared when the solutions were used in normal strength.

MAJOR MARION I. JEFF DAVIS, M. C., A. U. S.: The soldier is supplied with two types of prophylaxis against vesicant agents. One is used as a prophylactic against the mustard gas agent and there is also one used as a prophylactic against lewisite burns. These are ointments. They have to be applied rapidly after contamination. If they are applied within a few minutes after contamination they work well particularly in the case of lewisite. This prophylactic agent for lewisite has a specific action and is capable of reversing the lewisite reaction with the cellular tissue up to a given time after contamination. The principle involved in this ointment and its formula are not divulged; however, it has now been distributed to several clinics throughout the country; the active principle is being used in the treatment of toxic arsenical reactions. Severe arsenical dermatitides have been treated with this agent successfully. It is put up in the form of an intramuscular injection and used as an injection four times a day during the first day and once daily thereafter for the next five days. The reports have been received that this agent has actually saved patients' lives who have developed severe arsenical dermatitis which otherwise would probably have resulted in death. The investigative work included in this paper brings out perhaps one important feature: the need for a great deal of further work in burns. The pathology of burns, the mechanism of vesiculation and the therapy of burns are fields in which the dermatologist has an opportunity to contribute his share.

METABOLIC CRANIOPATHY

A CLINICAL AND ROENTGENOLOGIC STUDY OF SO-CALLED HYPEROSTOSIS FRONTALIS INTERNA

ARTHUR GROLLMAN, M.D., PH.D.

DALLAS, TEXAS

AND

J. P. ROUSSEAU, M.D.

WINSTON-SALEM, N. C.

Metabolic craniopathy has been defined as "a syndrome characterized clinically by variable and protean manifestations of a metabolic, endocrine and neuropsychiatric nature and roentgenologically by characteristic thickening of the internal tables of the skull."¹ The condition has been commonly referred to as hyperostosis frontalis interna, but this is a less suitable designation since the changes observed in the skull do not appear to contribute to the clinical picture nor are they probably an essential part of the syndrome. The changes in the skull are moreover not always limited to the frontal bones, and hence the designation metabolic craniopathy would appear preferable. Other designations which have been used for certain forms of this disorder are the eponyms Morgagni's and Stewart-Morel's syndrome and the terms "cranial hyperostosis of the insane" and "calvarial hyperostosis." These too fit the condition less satisfactorily, however, than does the designation metabolic craniopathy.

Although metabolic craniopathy is a relatively common condition, found in about 1 to 2 per cent of all patients admitted to hospitals, it is only since 1928 that the condition has been recognized as a clinical entity. In that year Stewart² described 5 patients with unusual

clinical features who at autopsy were found to have hyperostosis of the skull. He drew attention to the association of mental symptoms and obesity with the observed localized cranial hyperostosis. Moore's³ survey of 6,650 x-ray films of the skull clarified the roentgenologic aspects of the disorder, established criteria for its diagnosis and clarified the confusing roentgenographic findings in the several types of cranial exostoses, puerperal osteophytes and senile hyperostosis and established our present concept of the pathognomonic bone changes in metabolic craniopathy as seen on x-ray examinations. Since Stewart's publication,² over 100 cases have been reported in the world literature.

CLINICAL MATERIAL AND METHODS

The present paper is based on a survey of the patients seen at the North Carolina Baptist Hospital. During the two and one-half year period between July 1941 and January 1944, approximately 1,620 examinations of the skull were carried out in the Department of Roentgenology for one cause or another. Of these, 78, or 4.1 per cent, revealed the presence of calvarial hyperostosis pathognomonic of metabolic craniopathy. Many of these patients were outpatients referred by physicians for x-ray study only and hence were not available for clinical study. In the vast majority of the cases an x-ray examination of the skull was requested because of unexplained headache. Disease of the sinuses and intracranial tumor were the disorders most often suspected by the referring physician. In less than 5 per cent of the cases was the true nature of the disorder suspected.

The clinical data presented in the present paper are based on an analysis of 40 patients in whom the diagnosis, as suggested by the history, physical examination and laboratory studies, was confirmed by the x-ray findings.⁴ In addition 2 patients were encountered with clinical findings typical of the disorder but without the pathognomonic x-ray evidence of the characteristic hyperostosis. It is now generally conceded that the changes in the skull are merely one characteristic of the disease and need not be present. Nevertheless, the objective x-ray findings remain to date the most constant and reliable and the characteristic feature of the disorder.

INCIDENCE

As has already been noted, the incidence of calvarial hyperostosis in our series of x-ray films of the skull was 4.1 per cent. This is considerably higher than that reported by Moore³ (1.2 per cent) but lower than that noted by Eldridge and Holm⁵ (25 per cent) in patients admitted to an insane asylum.

The 42 patients whom we have studied clinically were encountered among a total of 4,200 individuals seen in the medical services of the North Carolina Baptist Hospital. The incidence of the disorder is thus approximately 1.0 per cent in a general hospital population. Metabolic craniopathy is thus far from being a rare condition.

AGE

The age distribution of our patients has been as follows: ages 20 to 29, 5; 30 to 39, 10; 40 to 49, 16; 50 to 59, 5; 60 to 69, 4. More than a third of the

4. Drs. Wingate M. Johnson, Elbert MacMillan and R. L. McMillan gave us permission to study and include 4 of their patients in this series.

5. Eldridge, W. W., and Holm, G. A.: The Incidence of Hyperostosis Frontalis Interna in Female Patients Admitted to a Mental Hospital, Am. J. Roentgenol. 43: 356, 1940.

patients were thus in the fifth decade of life when they first presented themselves for diagnosis, although in most cases the symptoms had been present for many years. The youngest of our patients was aged 21. The disease apparently, judging from the history, has a slow and insidious onset and probably begins in early life. The youngest patient on record in whom hyperostosis was evidenced in the x-ray film was aged 7, and in 5 of our own cases the changes in the skull were pronounced before the age of 30. In most cases, however, the condition is a disorder of middle life.

SEX

The condition, as has been pointed out by all previous observers, is predominantly one affecting the female sex. Only 1 of our patients was a man. This compares with the results of previous observers,⁶ who also

Fig 1.—A 49 year old patient showing the typical obesity of metabolic craniopathy. The principal symptom of complaint was intractable headache. Note the megalomastia and rhizomelic type of obesity often erroneously referred to as "pituitary obesity."

found that 97 to 98 per cent of the patients were women. The 1 male patient in our series was a 33 year old salesman who complained of trembling, nervousness, insomnia, periodic attacks of blindness and generalized weakness. Physical examination was entirely negative except for bilateral megalomastia, which, according to the patient, was a familial characteristic shared by several other male members of his family.

HEREDITY

Metabolic craniopathy frequently affects several members of the same family, being inherited as a dominant character.⁷ The family history of a number of our patients suggested the existence of the disorder in their

relatives. In one instance the x-ray examination of the skull of a paternal uncle (an inmate of a mental asylum) of one of our patients revealed the existence of the disease.

SYMPTOMATOLOGY

The symptoms of metabolic craniopathy are protean and variable. They consist of metabolic, endocrine, hypertensive and neuropsychiatric manifestations. Although only one of these general groups of symptoms may be predominant in any individual case, there are usually manifestations of at least two or more of them. In our series of 42 patients, 14 showed manifestations of neuropsychiatric, metabolic and endocrine dysfunction. In 13 the neuropsychiatric manifestations alone were outstanding. In 8 a combination of neuropsychiatric and metabolic abnormalities were predominant. In 5 cases neuropsychiatric and endocrine disturbances were outstanding. In the remaining 2 cases the changes in the skull were merely an incidental finding, and it was only on questioning that evidence of neuropsychiatric manifestations was elicited. One of these patients was brought to the hospital by hypertensive cardiovascular disease and chronic nephritis, where she died of uremia. The hyperostosis of the other patient was discovered incidentally during the study of a control series of 50 female patients in the fifth decade of life to determine the incidence of calvarial hyperostosis in the general hospital population. Her principal complaint was due to chronic cholecystitis.

Metabolic Disturbances.—The principal metabolic disturbance noted in this condition is obesity. This was observed in 23 of the 42 cases covered in this report. The obesity is usually of the rhizomelic type with megalomastia, which has so frequently but without any rational basis been designated as the "pituitary" type of obesity (fig. 1).

Basal metabolic determinations varied in most cases within plus or minus 10 per cent of the normal. In only 2 cases did the basal metabolic rate deviate beyond these figures, being minus 15 per cent in 1 case and minus 18 per cent in another. There was no evidence of hypothyroidism in these cases.

The blood cholesterol, which was determined in 18 of the cases, was within normal limits (180 to 220 mg. per hundred cubic centimeters).

There was no evidence of any disturbance in the calcium and phosphorus metabolism. The blood levels of the serum calcium and inorganic phosphate were normal in the 26 instances in which these determinations were made.

Hyperglycemia is considered by Bartelheimer⁸ as a symptom of hypophysial diabetes in hyperostosis frontalis interna, but in our series of patients this was encountered in only 3 instances. In 2 of these the glycosuria was mild and was controlled by dietary restriction. In the other 3 there was relative refractoriness to insulin, and large doses did not effectively control the hyperglycemia. In 12 other patients in whom obesity was a prominent symptom the dextrose tolerance did not differ from that observed in otherwise normal obese individuals.⁹

Endocrine Disturbances.—Approximately one half of all the patients in our series have manifested some disturbance usually attributed to the endocrine organ-

⁶ Grollman¹; Eldridge and Holm²; Kries, P. T., and Lelover, H. E.: Metabolic Craniopathy: Hyperostosis Frontalis Interna, *Ann. Int. Med.* 14: 1858, 1938; Samson, M.; Caron, S., and Martin, C. A.: Syndrome d'hyperostose frontale interne a caractere familial, *Laval med.* 7: 140, 1942.

⁸ Bartelheimer, H.: Die hyperostosis frontalis interna als Symptom des hypophysären Diabetes, *Deutsche med. Wochenschr.* 65: 1129, 1939.

⁹ Grollman, A.: Essentials of Endocrinology, Philadelphia: J. B. Lippincott Company, 1941.

The principal endocrine disturbances were related to the reproductive system, with abnormalities of menstruation not associated with any demonstrable pelvic disease. In 9 of the patients, amenorrhea was outspoken. The menarche usually occurred normally, but gradual cessation of the menses began at the age of 18 or 20 and in some instances the amenorrhea had continued over a period of many years.

Hirsutism (fig. 2) is the other prominent manifestation which we have encountered in 12 of the 42 cases. Since these symptoms are usually associated with obesity and hypertension, one can readily see how this condition might mistakenly be diagnosed as the Cushing syndrome. As a matter of fact this diagnosis had been made elsewhere in 2 of the cases in this series and in 1 case an exploration of the adrenals had been carried out.

Hypertension.—Hypertension identical to that seen in benign hypertensive cardiovascular disease has been observed in 16 of our 42 patients. This is a much higher frequency than one would expect if the hypertension was merely a coincidental occurrence, and we therefore believe that this represents another of the protean manifestations of the disease.

Neuropsychiatric Disturbances.—Neuropsychiatric manifestations constitute the most prevalent symptoms observed, being present in over three fourths of all patients. In 30 of our 42 patients a diagnosis of psychoneurosis had been made at some time during the patient's life.

The neuropsychiatric manifestations did not conform to any specific syndrome. This fact has also been noted by Eldridge and Holm,⁸ who observed in their patients thirteen of the twenty-two types of psychosis recognized by the American Psychiatric Association. Schiff and Trelles¹⁰ describe the neuropsychiatric disturbances observed in hyperostosis frontalis as consisting of (1) intellectual slowness with depression and anxiety, (2) disturbances of temperament and character and (3) protective neuroses. Personality changes, egocentricity, hypochondriasis, general nervousness and the other usual psychoneurotic manifestations are commonly observed. Easy fatigability, muscle weakness, dimness of vision, diplopia, dizziness (without any evidence of ocular disease) and subjective disturbances in gait and equilibrium are frequent complaints. Cranial nerve defects, narcolepsy, convulsive seizures, mental deterioration and dementia are less common manifestations.

Headache was a very common complaint, being present in 19 of the 42 patients of our series. It is commonly frontal but may be occipital or may be referred to the top of the head or to the nuchal area. In several cases the headache was disabling and was the principal complaint. The refractoriness of this headache to the usual methods of therapy is striking. In the more severe cases ergotamine tartrate, aminopyrine and the other usual preparations were found to be ineffective.

Major psychoses are common in patients suffering from metabolic craniopathy. Four of our patients had

at some time required institutional confinement. These patients were suffering from depression.

Hysteria, with diverse manifestations, is frequently observed in metabolic craniopathy and was noted in 8 of our patients. In 1 the conversion hysteria was of the paralytic type, with hysterical paralysis and anesthesia of the left lower extremity. In 2 patients there were attacks of periodic blindness and in 2 periodic deafness, apparently hysterical in origin. One patient suffered from chronic attacks of jacksonian epilepsy. Another patient gave a history of a single acute attack of convulsions and coma lasting for several days. Somnolence was a symptom in 2 patients, dizziness and fainting spells in 3.

ROENTGENOLOGIC CONSIDERATIONS

We have found positive bone changes in the skull in 98 per cent of the patients in whom typical clinical symptoms were present. In practically every patient with the usual endocrine, metabolic and neuropsychiatric

Fig. 2.—A 39 year old patient with metabolic craniopathy. Note the facial hirsutism often seen in this disorder. In addition the patient manifested the typical obesity, hysterical paralysis of the left leg, and amenorrhea of ten years' duration.

manifestations of the disease, pathognomonic bone changes in the vault can be demonstrated on the roentgenogram. The failure to see typical bone changes, however, does not exclude the possibility of the syndrome, as clinicians interested in this disease can with careful study arrive at a diagnosis in a small percentage of cases on the basis of clinical findings alone. There are also a certain number in whom typical x-ray changes are demonstrated and in whom subsequent clinical investigations fail to elicit the expected symptoms. We feel that in all probability these patients will in time develop clinical manifestations, but we have no proof of this nor do we know how soon after x-ray bone changes occur such manifestations will develop, since our observations have been over too short a period of time.

The characteristic x-ray changes consist essentially in the deposition of cancellous bone of great density on the inner table of the frontal bone (fig. 3). This formation consists of benign noninflammatory osseous tissue, affecting primarily the compact bone of the inner table. In a small percentage of cases it will later involve the diploe between the tables (fig. 4). In

10 Schiff, P. and Trelles, J. O.: Syndrome de Stewart Morel (hyperostose frontale interne avec adipose et trouble mental) d'origine traumatique, *Encephale* 24: 768, 1931.

the majority of the cases the lesion is entirely limited to the squama frontalis, the condition which we recognize as typical hyperostosis frontalis interna. Occasionally there is involvement of the orbital plate of the frontal bone, the inner table of the parietal bone or, less commonly, the structures in the middle fossa at the base of the skull, especially the temporal or sphenoid bone and the bony structures of the hypophysial fossa (fig. 5). Diffuse calvarial hyperostosis involving the entire vault has been reported by Moore,³ and Schiller¹¹ has reported extracalvarial bone changes in the mandibles. In none of our cases were changes demonstrated outside the calvarium. Knies and Lefever⁷ feel that distinction between the various subgroups as outlined by Moore is somewhat arbitrary and that care must be exercised lest thought become more confused rather than simplified.

In none of our cases were remote hyperostotic bone changes unassociated with the characteristic changes of the frontal bone found in the vault. We feel that in

Fig. 3.—Posteroanterior and lateral appearance of the skull in a case of metabolic craniopathy showing the typical deposition of cancellous bone on the inner table of the frontal bone.

all cases showing the classic x-ray appearance the inner table of the frontal bone is primarily involved and that in approximately 2 per cent of these lesions will be seen elsewhere in the vault. In all cases there is thickening and sclerosis of the inner table of the frontal bone, which, in some cases, may be as great as 3 to 5 cm. in thickness (fig. 6). The outer table is always spared and the external diameter of the calvarium is not altered. Usually the changes are bilateral and symmetrical. From these observations we may perhaps be justified in concluding that the x-ray evidence of metabolic craniopathy is hyperostosis frontalis interna and that changes remote from the frontal bone represent secondary variations of this primary change.

If this criterion is adhered to, the differential diagnosis of this syndrome from the hyperostoses associated with acromegaly, osteitis deformans, tuberculous and syphilitic osteomyelitis, leontiasis ossea, cranial osteoma, sarcoma, metastatic cancer, underlying hemispherical meningioma and senile hyperostosis will become less difficult and this condition may be diagnosed with a high degree of accuracy on roentgenologic evidence alone.

DIFFERENTIAL DIAGNOSIS

Because of the neuropsychiatric manifestations of metabolic craniopathy the condition is frequently diagnosed as "psychoneurosis."

The obesity, hypertension, hirsutism and amenorrhea often lead to the diagnosis of Cushing's syndrome. There should, however, be no cause for confusion between the two conditions, since patients with metabolic craniopathy lack many of the outstanding features of true Cushing's disease. One does not observe in metabolic craniopathy the osteopetrosis, acrocyanosis and purplish striae which are characteristic of Cushing's syndrome.¹² Moreover, the course of the disease in the two conditions is entirely different, being rapidly progressive in Cushing's syndrome and relatively chronic without rapid progression in metabolic craniopathy. Except for the hirsutism, there is no evidence of true masculinization in metabolic craniopathy. One does not find an enlargement of the clitoris or the masculine voice observed in most patients with androgenic tumors of the adrenal gland or with arrhenoblastoma.

The 17-ketosteroid content of the urine has been shown to be of considerable significance in the diagnosis of Cushing's syndrome and disorders of the adrenal cortex. It was thought, therefore, of interest to investigate the excretion of this steroid in the urine of patients suffering from metabolic craniopathy in whom amenorrhea and hirsutism were prominent features and in whom one might therefore suspect some abnormal androgenic activity of the adrenal cortex. In 10 patients on whom such studies were made the daily 17-ketosteroid excretion was 3 to 7 mg. This is entirely within the normal limit. Such determinations might be useful as an added laboratory aid in the differential diagnosis.

TREATMENT

Metabolic craniopathy is a progressive chronic disorder, the more severe cases terminating at times in actual dementia. The majority of the cases, however, show little progression, with long continued morbidity. In most of our patients, symptoms had been present over a period of from two to fifteen years.

Among the various forms of therapy which have been suggested are the administration of chondroitin, aminoacetic acid or anterior pituitary and irradiation of the pituitary-hypothalamic area. In our own experience no form of therapy has proved of any demonstrable permanent value, and any apparent beneficent effect has probably been the result of suggestion. In several of our patients in whom the pituitary-hypothalamic area was irradiated striking improvement has occurred, but in other cases this form of therapy has been of no apparent value. In most cases the obesity has been controlled by dietary restriction, but in many cases, even on a low caloric diet, loss in weight has been minimal.

COMMENT

It has been questioned whether hyperostosis frontalis interna represents a real clinical entity.¹ Because of the chronic nature of the disease, few of the patients have come to autopsy and hence there is lacking any

12 Grollman: *Essentials of Endocrinology*, pp. 82-83

pathologic basis to which one might attribute the disorder. From a clinical standpoint we believe, however, that the disease does represent a definite entity, which when taken in conjunction with the specific roentgeno-

Fig 4—Appearance of the skull in a case of metabolic craniopathy, showing the involvement of the diploe between the tables in addition to changes on the inner table of the frontal bone and wings of the sphenoid

logic findings may be differentiated as a distinct disease process.

As regards the pathogenesis of the disorder, the nature of its symptoms would lead one to assume that the basic disorder is in the hypothalamic area of the brain. This portion of the diencephalon could give rise to the diverse symptomatology and protean manifestations which one observes in metabolic craniopathy.

Fig 5—A case of metabolic craniopathy with involvement of the inner table of the frontal bone, the structures of the middle fossa at the base of the skull, and the squamous portion of the temporal bone

Further pathologic studies, however, are necessary before this hypothesis can be established.

In a few cases reported in the literature cerebral degeneration in the form of cortical atrophy has been

demonstrated.¹³ Although several authors have pointed to the endocrine features of the disease as evidence of an endocrinopathy being the basis for the disorder, there is no proof to support this view. In the 2 patients of our series who have come to autopsy no abnormalities of the pituitary, thyroid or adrenals could be demonstrated.

SUMMARY

1. A study was made of 42 patients suffering from metabolic craniopathy.

2. X-ray findings in 78 patients manifesting the disorder and in a control series of 50 patients were investigated in order to establish the roentgenologic basis for the diagnosis.

3. The 17-ketosteroid excretion in patients with metabolic craniopathy displaying metabolic and endocrine disturbances has been shown to be normal. In patients

Fig 6—Hyperostosis of the frontal bone and diploe, the new bone deposit being 4 cm. in thickness

with similar symptoms which are due to adrenal cortical dysfunction, the 17-ketosteroid content of the urine is elevated.

4. Metabolic craniopathy is considered to be a definite clinical entity of relatively frequent occurrence.

Fluid Structures of the Body.—The fluid structures of the body consist of three parts, the blood, the intracellular fluid and the interstitial fluid, the sum total of which constitutes 70 per cent of the body mass. Of this, 5 per cent of the body weight (35 liters in a person of 70 Kg.) is circulating plasma, 50 per cent (35 liters) intracellular fluid and 15 per cent (10.5 liters) interstitial fluid. This last, which includes the lymph, is the most labile of the three, for in order to preserve intact the other two it must undergo a constant shift in amount and, to a less extent, in electrolyte content.—McLester, James S.: *Nutrition and Diet in Health and Disease*, Philadelphia, W. B. Saunders Company, 1943.

HYPERTENSION

THE EFFECT OF ACTIVITY, REST, NATURAL SLEEP, SODIUM AMYTAL, PENTOTHAL SODIUM, CHLORALOSE AND ETHER ON EXPERIMENTAL NEUROGENIC HYPERTENSION AND OF REST AND SODIUM AMYTAL AND ANESTHESIA ON HYPERTENSIVE PATIENTS

KEITH S. GRIMSON, M.D.

CHARLES E. KERNODLE JR., M.D.

AND

HENRY C. HILL, M.S.

DURHAM, N. C.

Restriction of activity, extension of periods of rest and natural sleep, and generous use of sedatives are commonly employed in the medical treatment of hypertension. Splanchnicectomy (Peet,¹ Craig and Adson,² Smithwick³ and others) or subtotal to total paravertebral sympathectomy, splanchnicectomy and celiac ganglionectomy (Grimson⁴) have been of value as occasional supplements to medical management. Selection of patients for surgery has proved difficult. The effect of rest and sodium amytal on hypertension determined by hourly blood pressure readings during twenty-four hours or more has been emphasized by many physicians as one of several important factors indicating the advisability of surgery.

Vasomotor instability evidenced by abnormal elevations of blood pressure during reflex or emotional stimulation has long been recognized in many patients and associated with the term "neurogenic hypertension." The function of the sympathetic nervous system in mediating such elevations of blood pressure and the important role of the carotid sinuses and cardioaortic depressor nerves in regulating blood pressure have been reviewed.⁵ Heymans and Bouckaert⁶ in 1931 presented the first of a series of studies demonstrating that elimination of the modulating function of the depressor nerves produces vasomotor instability and a persistent neurogenic hypertension in dogs. Similar studies by Koch and Mies,⁷ Dautrebande,⁸ Nowak and Walker,⁹ Thomas and Warthin,¹⁰ Grimson¹¹ and Schafer¹² have been reviewed.⁵ Total sympathectomy effec-

tively reduces experimental neurogenic hypertension. Splanchnicectomy alone does not. The fundamental observations of Goldblatt and his colleagues¹³ in 1934 initiated an extensive investigation of renal factors in hypertension. These studies have afforded little encouragement for sympathectomy and have not yet produced a satisfactory therapeutic agent.

The nature of the hypertensive disease process present in many patients is obscure. We feel that elements of abnormal blood pressure regulation, abnormal renal function and vascular pathologic conditions, together with other factors as yet unknown, may all be present in many hypertensive patients in varying degrees. We also feel that in some patients faulty blood pressure regulation or a neurogenic element may be an initiating and a major perpetuating factor. The disturbed pressor depressor equilibrium of such patients would effect through the sympathetic nervous system an increase of peripheral resistance throughout the body. Subsequent vascular disease and renal humoral or metabolic change would also affect the entire vascular bed. Should medical management fail in hypertension of this variety, surgical intervention would be indicated. The effectiveness of sympathectomy should increase as it is extended from the original limited splanchnicectomies to include more or all of the body. A test that could determine the presence of a neurogenic element would be valuable.

Because of these several considerations we feel that this experimental study of the effect of activity, rest, sedation and anesthesia on experimental neurogenic hypertension in dogs is warranted.

ACTIVITY, REST AND NATURAL SLEEP

The technics conventionally employed for blood pressure determination in dogs require positioning and training and preclude determinations during normal emotional and physical activity, rest and natural sleep. We¹⁴ have devised a technic that employs small sterile buried iliac and femoral cuffs and pressure sacs connected through fine plastic tubing to a pressure mercury and a recording water manometer. This technic permits pulse rate and mean systolic blood pressure determination at any desired moment without disturbing the animal. The average and the range of the blood pressures of 4 normal dogs were determined during varying stages of activity and during natural sleep. Two typical responses are represented in figure 1. The blood pressure and pulse average and range were elevated during activity and low during rest and natural sleep. Neurogenic hypertension was developed in 4 dogs by excision of the carotid sinuses and division of the vago-depressor-sympathetic trunk of one side and the depressor nerve of the opposite side. The blood pressure range and average of two of these dogs is represented in figure 2. It is evident that fluctuations of blood pressures during various stages of activity exceeded those observed in the normal dog. The blood pressures during rest and natural sleep of 3 of the 4 neurogenic hypertension dogs were lower than the active blood pressures but higher than similar pressures in the normal dogs (fig. 1). One of the 4 dogs (dog 2, fig. 2) had no reduction of the hypertension during

sleep. The pulse rates of the neurogenic hypertension dogs exceeded those of the controls and fluctuated more widely with variations of activity.

SODIUM AMYTAL AND PENTOTHAL SODIUM

The effect of sodium amytal on blood pressure was observed in 5 normal and 6 neurogenic hypertension dogs. The sodium amytal was given in divided doses during three or four hours in amounts averaging in all 0.2 Gm. per dog. This produced light sleep. The blood pressures were taken before and after the sodium amytal by direct arterial puncture. The positioning of the dog for arterial puncture after sodium amytal produced some restlessness. The neurogenic hypertension dogs employed had been prepared by elimination of the modulator or depressor nerves as described some three months before the experiment. The effect of the sedative on the blood pressure is illustrated in figure 3. An elevation occurred in 2 of the control animals, a lowering in 2 and no appreciable change in 2. An elevation occurred in 2 of the neurogenic hypertension dogs, a lowering in 3 and no change in 1.

The effect of pentothal sodium anesthesia was determined on 5 normal, 6 neurogenic hypertension and

in 3. It rose in 1 of the neurogenic hypertension group and dropped in 5. The final blood pressures of these 5 remained at definite hypertension levels. It rose in 3, dropped in 3 and remained unchanged in 1 of the renal hypertension animals.

Fig. 1.—Blood pressure and pulse range of 2 normal dogs. The pressures were obtained by an arterial cuff technique without disturbing the animals. Some lowering of pressure occurred during rest and natural sleep.

7 renal hypertension dogs. The neurogenic hypertension had been developed three to eleven months before the experiment. The renal hypertension was produced by placing tight silk or linen capsules about both kidneys from one to eleven months before the experiment. Blood pressures were taken by arterial puncture during this period to familiarize each animal with the procedure. The last blood pressure was taken in a dark quiet room just before the experiment. Pentothal sodium in a 2.5 per cent solution was then introduced through the saphenous vein until the anesthesia was sufficient to prevent pain reflexes. A second arterial puncture was performed four to ten minutes after the induction to determine the blood pressure under anesthesia. Respiratory arrest and pronounced cyanosis occurred in certain dogs of the neurogenic hypertension group. These experiments were repeated until satisfactory respiration was maintained. The neurogenic hypertension animals required slightly more pentothal sodium for anesthesia than did the control or the renal hypertension groups. The effect of pentothal sodium anesthesia is illustrated in figure 3. The blood pressure rose in 2 of the control dogs and dropped

Fig. 2.—Blood pressure and pulse range of 2 of 4 neurogenic hypertension dogs. Dog 1 demonstrates the greatest lowering observed during natural sleep and dog 2 the least. The blood pressures of the neurogenic hypertension dogs during sleep did not reach the low values observed in the normal dogs (fig. 1).

CHLORALOSE AND ETHER ANESTHESIA

The effect of chloralose anesthesia on blood pressure was observed in 4 normal and 5 neurogenic hypertension dogs (fig. 4). The blood pressures were determined by arterial puncture before and after the intravenous administration of 0.08 to 0.1 Gm. of chloralose per kilogram of body weight. Some lowering of blood pressure occurred in 2 of the normal dogs and a

Fig. 3.—The effect of sodium amytal sedation on the blood pressure of 6 normal and 6 neurogenic hypertension dogs is demonstrated on the left. The effect of pentothal sodium anesthesia on 5 normal, 6 neurogenic and 7 renal hypertension dogs is represented on the right.

moderate elevation in 2. A lowering of blood pressure occurred in 1 of the neurogenic hypertension dogs, elevation in 2 and no change in 2.

The effect of ether anesthesia on blood pressure was determined in 4 normal and 4 neurogenic hypertension dogs. Arterial puncture blood pressures were taken

before and after the induction of a deep third plane ether anesthesia. Some lowering of blood pressure occurred in 1 and little change in 3 of the control dogs. The 4 neurogenic hypertension dogs demonstrated a definite lowering. The final blood pressures remained in the hypertensive range.

COMMENT AND CLINICAL STUDY ON REST AND SODIUM AMYTAL AND ANESTHESIA

Repeated blood pressure determinations by an arterial cuff method have demonstrated a range of blood pressures in normal dogs that is higher during activity and lower during rest and natural sleep. The range is greater in neurogenic hypertension dogs. Active blood pressure readings were high. Readings during natural sleep were lower but at no time approached the low level observed during sleep in normal dogs. Sodium amytal did not significantly alter the blood pressures of neurogenic hypertension dogs. Chloralose anesthesia effected little change. Deep anesthesia under pentothal sodium and ether lowered the blood pressures to approximately the same hypertension values as were observed in the neurogenic hypertension dogs during natural sleep. Pentothal sodium did not significantly alter the blood pressure of 7 renal hypertension dogs. These studies would indicate that a neurogenic hypertension produced by a disturbance of blood pressure regulation will persist although at times somewhat reduced through sedation, anesthesia or natural sleep.

Interpretation of these findings into terms of clinical hypertension must be done with reservation. It seems well established that clinical hypertension is effected by an increase of the peripheral resistance. Components of disturbed blood pressure regulation or neurogenic hypertension, pathologic change, particularly arteriolar sclerosis, or renal circulatory change altering metabolism or producing a renal pressor substance may play varying roles in affecting the increase of peripheral resistance. The experiments would suggest that rest, natural sleep, sedation or anesthesia may moderately lower the blood pressure of a neurogenic hypertension. They also suggest that a neurogenic hypertension may

is illustrated by a review of the test as employed on the first 20 patients treated by paravertebral sympathectomy. This procedure, although limited somewhat by anatomic variations and by nerve regeneration, accomplishes sympathetic denervation of most of the peripheral vascular bed throughout the body. Rest and

Fig. 5.—The rest and sodium amytal tests of 10 patients who were treated by paravertebral sympathectomy and had a definite lowering of blood pressure are represented in group I. This is contrasted with similar tests of 5 patients who had no lowering of blood pressure in the supine position after sympathectomy, group II.

Fig. 6.—The rest and sodium amytal tests of the patients illustrated in figure 5 three to nine months after paravertebral sympathectomy. The 10 patients, group I, with definite reduction of blood pressure could not be differentiated from the 5 patients with no reduction in the supine position, group II, by the preoperative rest and sodium amytal tests (fig. 5).

sodium amytal tests were employed before the sympathectomy and at intervals of three to nine months after the sympathectomy. These were frequently preceded or followed by control twenty-four hour periods of hourly blood pressure determinations that presented a similar curve to that obtained with the sodium amytal.

Rest and sodium amytal tests before operation were separately plotted and then shuffled. Four observers attempted a prediction of which patient would be benefited by sympathectomy and failed. The rest and sodium amytal tests three to nine months after sympathectomy were then examined. Ten patients were selected as showing by the postoperative rest and sodium amytal test an appreciable lowering of the supine blood pressure. Five patients were selected as showing by this test alone no change in the supine blood pressure. Three patients with intermediate results, 1 with a polycythemia vera and another with a Cushing's syndrome were discarded. The preoperative tests of the 10 patients that later showed appreciable lowering of blood pressure are illustrated as group I in figure 5 and compared with the preoperative tests of the 5 patients that later had no lowering of blood pressure, group II. It was impossible to determine by the tests which patients would receive benefit from surgery. Figure 6 represents the rest and sodium amytal tests of the same groups of patients three to nine months after sympathectomy.

The effect of anesthesia was determined from the anesthetist's record of the first operation of these 15 patients. Ethylene or ethylene-ether anesthesia was employed. The blood pressure rose after anesthesia and before operation in 12 patients, remained the same in 2 and decreased slightly in 1. No difference existed between groups.

Fig. 4.—Effect of chloralose and of ether anesthesia on the blood pressure of normal and of neurogenic hypertension dogs.

persist under these conditions and that a negative rest and sodium amytal test may not eliminate the possibility that an element of a neurogenic nature may be present.

Rest and sodium amytal tests aid medical evaluation of the hypertensive patient. The importance of the sodium amytal test in the clinical evaluation of a patient should not, however, be overemphasized. This

CONCLUSION

Experimentally and clinically the blood pressure altering effect of rest, sedation or anesthesia has been found variable. Etiologic assumption or surgical prognosis based principally on rest and sodium amytal or anesthesia tests may be misleading. The blood pressure lowering effect of these tests clinically should be but one of many factors considered in the evaluation of the hypertensive patient.

ABSTRACT OF DISCUSSION

DR. GEZA DE TAKATS, Chicago: The significant experimental findings of Grimson and his associates indicate that the neurogenic hypertension in the dog does not respond remarkably to the customary use of barbiturates or sleep, which are so frequently employed in selecting patients for sympathectomy. The neurogenic hypertension of the dog, produced by section of the buffer nerves, may not be identical with the essential hypertension in man. There is good evidence that the buffer nerves are intact in essential hypertension. In my own series the best results with splanchnic nerve section have been obtained in young or middle aged women who have had toxemia of pregnancy or eclampsia, thus an organic vascular disease affecting among others the renal parenchyma. In this group, which consists of an internist, an ophthalmologist and a surgeon, a three day schedule is being used for a preoperative study of the hypertensive patient. As Dr. Grimson stated, the sodium amytal test is not always conclusive. We have had certain cases that indicated through the carbon dioxide pressor test whether the central mechanism is active or not. A patient with a late grade 3 hypertension who showed on biopsy a late benign renal sclerosis gave a slight response to the carbon dioxide pressor test. On the other hand, a younger patient with other tests showing early grade 1 hypertension with considerable vasomotor activity gave an exaggerated response to carbon dioxide. The block of the paravertebral sympathetics as a preoperative test, just like high spinal anesthesia, cannot be a good test for operability, since it is especially apt to cause a definite drop in blood pressure in the older, sclerotic group by causing a sudden failure in venous return. In face of these difficulties the lack of pronounced organic changes and fall in blood pressure to a minimum requirement of 150 systolic, 100 diastolic after rest or sedation still remain the safest criteria for operability.

DR. EMMET B. BAY, Chicago: Dr. Grimson's work in both animals and man has great validity. Any single test is obviously a precarious thing on which to base one's judgment with respect to indications for operation. The sodium amytal test may be largely left out of our armamentarium because some of Dr. Grimson's patients had negative sodium amytal tests and yet had very good response to the operation. It leaves us, however, in great difficulty. The surgical procedure is a major one. We would like to employ it for younger people in whom there was no serious organic change in the precapillary arterioles or in the kidneys. We, as internists, don't like to suggest an operation to patients when we know that so many of these cases have a relatively benign course for so many years. We should like to pick out those in whom the course is going to be a malignant one, pick them out early and attempt to correct this situation before serious irreversible damage has been done. This procedure was, wisely, first used only on elderly patients for the most part who were doomed to die unless something was done about it in a very short time. The fact that as many of them received some improvement as did indicates that it should be included in our thinking about the treatment of hypertension still, but we all hope that those who are working on the physiology of this common disease will find some method of management that will lead to improved care for this large number of patients.

DR. KEITH S. GRIMSON, Durham, N. C.: One impression that Dr. de Takats' report has unintentionally given might be corrected. He demonstrated an outline for a three day pre-operative evaluation of the hypertensive patient. Actually many patients should be evaluated in the hospital for three weeks or more before surgical treatment should be considered.

PSYCHIATRIC SELECTION OF MEN
FOR THE ARMED FORCES

RAYMOND W. WAGGONER, M.D.

Psychiatric Consultant, Selective Service System

ANN ARBOR, MICH.

COLONEL WILLIAM C. MENNINGER

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

COMMANDER FRANCIS J. BRACELAND

MEDICAL CORPS, UNITED STATES NAVAL RESERVE

The importance of the psychiatric aspects in the selection of men for the armed services was recognized by psychiatrists long before the onset of the present war. In 1918 it became so apparent to General Pershing that better methods should be used in screening out those individuals who would be unable to make a satisfactory military adjustment that he cabled to the Chief of Staff in Washington as follows: "Prevalence of mental disorders suggests urgent importance of intensive efforts in eliminating mentally unfit from organization of new draft prior to departure from United States." During the last war attempts were made to screen all recruits at mobilization centers. In some centers most of the recruits were seen by psychiatrists with adequate screening in the light of psychiatric knowledge at that time. In other centers no psychiatric examination was made or it was most unsatisfactory. In a considerable number of instances rejection was recommended by the neuropsychiatric examiner but the recommendation was overruled by the line officer or command surgeon. At the same time the number of neuropsychiatric casualties in the last war was great (41,646) and the postwar problem of care has been stupendous, the total cost of \$30,000 to \$35,000 per man being greater than for any other single group of casualties.

In the summer of 1940 when it was apparent that we were likely to be involved in the present conflict, Dr. Winfred Overholser wrote a detailed and excellent summary of the problem to President Roosevelt, calling attention to the need for the establishment of an adequate psychiatric screening program which could be used when the time came for rapid mobilization of a large army. Considerable thought was given to the subject by psychiatrists and Selective Service planning groups. During the latter part of 1940 and the first of 1941 the Selective Service System established plans and began holding seminars in various parts of the country. This psychiatric program was under the direction of Dr. Harry Stack Sullivan and an advisory committee. The purpose of these seminars was to indoctrinate the local board physicians with the need of and a method of recognition of psychiatric problems and to help them to weed out at the local board level those registrants who would be unable to adjust satisfactorily to the military service. At that time the American Psychiatric Association, through its special committee appointed to deal with wartime problems, was aiding in the development of plans for psychiatric examinations of prospective members of the armed forces.

In several states plans were developed to secure information which would aid in the proper psychiatric selection of recruits. Through cooperation of the

Selective Service System, the Army and the Navy, and with the advice from representatives from the American Psychiatric Association, military psychiatric standards were established. These standards if followed were presumed to cause the rejection of those who would likely fail in military service. The tendency was to reject all persons who showed any evidence of psychiatric disorder. That this attitude has changed is evidenced by War Department Technical Bulletin TB MED 33, which says in part "There is accumulating evidence that many individuals with minor personality deviations and mild neurotic trends can be of service in the armed forces. It is believed that, on the basis of previous directives, many such men are now being rejected at induction stations on neuropsychiatric grounds. The acute need for manpower makes it necessary to admit all individuals to serve in the armed forces who have a reasonable chance of adjusting to such service. The neuropsychiatric study should be made on a longitudinal basis and not on a cross section. The Medical Survey Program was developed by Selective Service to make just such a longitudinal survey possible.

In the present conflict the size of the armed forces is far larger than that of the last war. The forces have been built up to this size in approximately three years. Psychiatric selection, which requires more time than physical selection, has been seriously hampered by this extraordinarily rapid mobilization.

The problem of selection from a psychiatric standpoint is of course to recognize those men who by the nature of their personality makeup will not be able to adjust satisfactorily in the armed forces. It was necessary, with no historical data, to prognosticate the future mental health of these individuals rather than to make the diagnosis of a disease process. Psychiatrists, no matter how well trained, were not prepared for this type of function.

Most of the psychiatrists at induction stations are civilian psychiatrists, and most of those who are in the armed forces have been commissioned out of civil life. These men have an inadequate understanding of the needs of the armed forces, even though they may have a fair idea of the stress to which servicemen may be subjected. As in other fields of endeavor there are both exceptionally well qualified psychiatrists and those who are poorly qualified. By virtue of the amount of work to be done and the shortage of men to do it, all available psychiatrists have been employed. It is perfectly obvious to many of us that some psychiatrists are doing an inadequate and unsatisfactory examination, especially at the induction stations. To quote further from TB MED 33 "Thus, a neuropsychiatric examination consisting of a few leading and suggestive questions such as 'Do you worry?' 'Are you nervous?' or 'Do you have headaches or stomach trouble?' is inadequate, and positive answers to such questions are not in themselves justifiable cause for rejection. Isolated signs, such as nail biting, slight tremor or vasomotor symptoms, are not disqualifying. Normal concern over the prospect of induction, as manifested by moderately moist palms or tenseness, should not be regarded as evidence of an incapacitating disorder. Rejection for neuropsychiatric reasons should be made only in those cases in which the history and examination clearly indicate the existence in the past and/or present of a personality disorder of partially or completely incapacitating degree." These poorly done examinations have in some cases resulted in the rejection

of men who should have been accepted, as well as the acceptance of many who should have been rejected. Much criticism of psychiatric rejections has been expressed by Selective Service board officials, by the Army officials and by the public. Some of this criticism is valid, but most of it is unjustified and has been the result of misunderstanding of the meaning of psychiatric rejection and of the seriousness of psychiatric casualties. In many instances this criticism can be considered a psychologic defense and projection mechanism on the part of the person offering it.

At the present time research is being carried on to develop what might be called a military personality profile. Psychiatric screening has been done on the basis of presumption of psychiatric disorders or indications of the possibility of its development not on the basis of established criteria or exact measurements as is true in the physical study. Therefore the more experienced and capable the psychiatrist making the examination and, within certain limits, the greater the amount of time allotted him, the more accurate will be his prediction as to the inductee's success or failure in the armed forces. It is hoped that, with the greater knowledge of the personality characteristics which lead to failure in the armed forces and of those which spell success, psychiatric selection will become progressively more accurate.

At the present time our job is not only to recognize the manifest cases of psychiatric disorder and those who are apt to develop a psychiatric disorder as a result of the stress of military life but also to select those individuals who will be unable to adapt themselves satisfactorily to military life. This includes the mentally deficient, the inept and the psychotic, as well as those with neurotic characteristics. It should be emphasized that persons with certain types of mild neurosis may do well in the armed forces. Service may resolve the basic conflict. Recognition of the psychopathic personality group is important because, although these individuals may not actually develop a serious psychiatric illness in the armed services, yet by virtue of their inability to adjust they may serve as a focus of infection of bad morale, which in turn may result in breaks in discipline and lead to disaster. This is typified in the description of a situation told by an Army officer who at one time had been placed in charge of a unit with a reputation for bad discipline, which under two or three previous commanding officers had become progressively worse. This man, instead of initiating his command by establishing rigid discipline, carefully observed the unit for a week and then picked out three men who, although they did not have any psychiatric deviations obvious to a lay person, did have psychopathic personalities. These men were discharged, and the unit almost over night changed from one with a very bad reputation to one with high morale.

Those individuals who present psychiatric problems in the service might be considered in four categories or groups. The first group would include those who are manifestly unfit for service and whose disability is obvious or becomes so during the course of a brief psychiatric examination. Such individuals are easily detected and account for a fairly large percentage of the neuropsychiatric rejections at induction stations. The second group are those who are questionably fit but with whom a more complete historical background, the need of observation or both is necessary in order to evaluate their fitness accurately. The historical

information obtained through the Medical Survey Program is particularly important in the selection of this group. In the naval service until the present, these cases have been detected at the naval training station or boot camps, where, after a period of observation and trial duty, the lack of fitness is demonstrated. The third group includes those who are potentially unfit but who may be able to adjust reasonably well for an indefinite but relatively short period of time. These men adjust well until the degree of stress becomes sufficiently severe to produce symptoms. They are separated from the service only after hospitalization study and medical survey. In the future large numbers of these should be detected by the historical information made available by the Medical Survey Program. The adjustment of these individuals usually becomes strained after the first six months. The peak period of discharge of these individuals occurs within the first twelve months of service. Finally, the fourth group would include those who, according to the best possible tests and the highest standards of psychiatric fitness, including an adequate historical background, appear to be normal, well integrated individuals. Not until such persons are confronted with the greater than normal stress of actual combat or prolonged operational duties do they manifest evidence of functional disability. It does not seem likely that any procedure can be set up which will accurately determine which individuals going through induction stations would break down provided they are in this fourth group.

At the present time the procedure for the selection is divided into two parts, the first phase being before the prospective service man reaches the induction station. Following registration, and if the registrant reports any difficulty which makes it apparent to the board that he might not be able to pass the induction station examination, he may be referred to a physician for examination either at the board's request or at his own request, or he may be referred to an advisory board for special examination. At the time of registration or, if registered, when he is considered for the reclassification which will lead to his induction, a survey is made of his previous social, medical and school history. This material is prepared by various regularly constituted individuals at the local board level on special forms for transmittal to the induction station. This survey, which is called the Medical Survey Program, was developed by the Selective Service System in conjunction with the Surgeon General's Office of the Army and Navy. Important procedures in the program are carried out by the use of certain forms.

Form 210 is designed to establish the identity of the individual in reference to treatment for mental illness. If this treatment has been in a state hospital, the registrant is disqualified at the local board level.

Form 212 carries medical and social history so arranged that the examiner at the induction station can determine at a glance the presence of positive or negative information of value. In case important information is available and is so noted by the checking of one of the questions, it is inscribed on the reverse of the form. This form is completed by a special field worker known as the medical field agent.

Form 213 is a composite report from five teachers so arranged that any consistent deviation from the normal will be called to the attention of the examiner by merely glancing at the composite form. This form is to be used for boys from 15 to 18 years of age at the time they

leave school for any reason other than transfer to another school.

Form 214 is to be used to obtain information about school adjustment when it is necessary to get this information from school records.

Only form 210 is to be used as the basis for rejection, and this should be carried out at the local board level. The other forms have information for the induction station psychiatrist and should give him important leads as to possible reasons for rejection or induction. Such procedures have been in use in several parts of the country over a period of many months. The program was established as a national program in October 1943. It is so designed as to give the examining physicians at the induction station the maximum amount of information about each registrant with the minimum amount of time necessary to utilize this information. As first constituted the Medical Survey Program was very comprehensive in its coverage of various factors relating to the adjustment of the individual. As is so frequently true in the development of any plan of this scope, some changes were necessary to suit particular problems in various parts of the country in order to yield a maximum of utilization with a minimum of difficulty. As the machinery of the plan has been developed, various changes have been made and will continue to be made in order to reach the highest degree of efficiency possible. Universal coverage of men forwarded has not yet been achieved but is constantly on the increase. It should be the responsibility of every psychiatrist, military or civil, to assist in this program in order that the aim of best possible selection may be achieved as soon as possible.

The second phase might be considered that which occurs at the induction station and during the early period of the registrant's military career. The induction station psychiatric examination is difficult. A number of factors tend to militate against a completely successful psychiatric study. First and foremost among these factors is the time element. While a reasonably good judgment can be based on a study of ten to fifteen minutes, in many instances so many have had to be examined that the time allotted to each may be reduced to one or two minutes per individual. Without other information, such an examination can be only of very superficial value. Second, not all examiners are of equal competence. Asking such questions of the selectee as "Do you worry?" or "Do you have stomach trouble?" and observing certain minor signs as mild vasomotor instability, mild tenseness results in an almost worse than useless psychiatric examination, and yet frequently this kind of an examination is the basis on which a man is rejected or accepted. It should be apparent that a justifiable rejection can be based only on a longitudinal study of the individual. It most certainly should not be based on an all too brief cross section examination of the individual at the moment of his induction station examination. To quote further from TB MED 33, "Information and time are oftentimes inadequate to establish accurate diagnoses. In many instances the symptomatology and/or behavior may make disqualification of the registrant necessary, although not sufficiently well crystallized to warrant the diagnosis of a clinical disease entity. To label a registrant with a diagnostic term in so brief an examination, without adequate data available, is unscientific, and unfair to the individual. Each clinical diagnosis as given in MR 1-9 will be based on adequate historical and examination evidence. In those instances where insufficient

data are available to arrive at a diagnosis and where it is the neuropsychiatrist's opinion that the registrant is not acceptable, he will indicate that the individual is disqualified as 'not suited for military service.'

In some sections of the country the induction stations are using an autobiographic social survey. This consists of a questionnaire which is given each registrant at the induction station and which he is to complete by the time he reaches the psychiatrist. Since the psychiatrist is usually last or next to last in the examining line, the registrant has ample opportunity for filling out the form during the course of his other examinations. This form has proved of considerable value in selection, but difficulties arise in connection with its use. In certain instances the individual refuses to put down all the information required or records inaccurate information, which at times may be misleading. This form cannot be used by illiterates. Some of the registrants tend to consider the psychiatric examination as a joke or to be very much frightened by it. Those reactions are in themselves a valuable index of the registrant's personality makeup. This plan, where used, supplements the information obtained by the Medical Survey Program.

There are important social implications involved in the examination of men for the armed forces. To many men who failed to be selected for service, this failure represents a threat to their self esteem and self confidence. This is particularly true with regard to certain types of psychoneurosis. A significant factor in the readjustment of the individual in his community is the fact that he frequently carried back with him a label which connotes maladjustment, the label being the result of a diagnosis made on the basis of a very brief examination. This diagnosis may make it more difficult for him to adjust to his home situation, for him to meet his associates if they know of his diagnosis, and for him to obtain reemployment or to return to his previous occupation.

There has been an unfortunately wide misinterpretation of the meaning of psychiatric rejection. Too many individuals have assumed that a neuropsychiatric rejection or a neuropsychiatric discharge from the armed forces signifies that the individual involved is "crazy." Even the rejectee involved may assume this to be the case. One person rejected for psychoneurosis looked the term up in the dictionary and found also the term psychosis, confused the terms, and both the patient and his family became extremely anxious for fear that within the near future it would become necessary for him to be committed to a state hospital. Whether this misinterpretation is wilful or the result of lack of understanding of the problem is not nearly so important as is the great harm which is done to those in the rejected group. It should be a part of our responsibility as psychiatrists and neurologists to clarify the issue whenever opportunity arises. Such clarification requires the development of better community understanding of psychiatric situations in general and of the psychiatric problem of the service man in particular. Education of the community concerning the role of psychiatry in war and in peace is urgently needed. In some respects psychiatry has been oversold; our need is to face the problems of community understanding squarely.

In a report of the first year's experience of the Information and Counseling Service at the Milwaukee Induction Station made by Miss Dorothy Paull, it is stated that "after a year of experimentation and observation we are more convinced than ever that the public has

no realization of the extent of emotional and mental illness in its midst or of the lack of resources to cope with it. Many young men are carrying on a tragic and lonely struggle attempting to make good against terrific odds of environment and unhealthy mental habits and family pattern." This is a clear and succinct statement of an important problem. With the information being developed under the Medical Survey Program the background for reeducation of the public and for a better understanding of the problem of psychiatric disabilities can be developed. This ought to be particularly useful when demobilization day comes. With the mass of information which will be available and which will remain confidential, those who are qualified to utilize it should be able to make a very real contribution to the better adjustment of our people.

Certain factors have been high lighted by our experiences in the psychiatric selection of men for the armed forces. The most important is perhaps the demonstration of such an alarming amount of mental ill health in our communities. The need for a more comprehensive mental hygiene program is obvious. It is our responsibility to provide and facilitate this program. The material available through the Medical Survey Program and through our experience at induction stations and in the armed forces, if properly analyzed, will serve as sign posts on the road leading to a better understanding of public needs and be put to excellent use by business, industry and the professions.

ABSTRACT OF DISCUSSION

DR. HANS DEUTSCH, Chicago: In these last three and one-half years I have gone through the difficulties which confront the psychiatrist in selecting men for military service. The first apparent difficulty was the lack of indoctrination before induction, and therefore the men manifested a lack of receptivity toward military discipline. Another important factor which might interfere with the obedience of a man joining the armed forces was negativism. From the start I favored the term "unsuitability" and instructing the man as well as the public that it is no reflection on the personality when a man is disqualified. Of prime importance is it to look at the man and his conduct during examination, and then if necessary look at the history. What we need are facilities for disposal of the man; not a rejection or acceptance but to decide where to put the man either in civilian or in military life. In that way we would not have so many men hesitant to join the armed forces or appeal for induction reexamination.

COLONEL LEONARD G. ROWNTREE, M. C., A. U. S.: In the thirteen million records to date we have had more than four million rejections. In addition to this we have many hundred thousand discharges. We apparently have a problem facing us in the nation of lack of physical and mental fitness that has never been suspected. Selective Service has attempted to deal with this problem in many different ways. We have been very fortunate in securing as adviser in this program Dr. Raymond W. Waggoner. We have provided for changes in this program when the need becomes apparent. We have requested the National Research Council to set up a committee consisting of Dr. Overholser, Colonel Menninger, in charge of the Psychiatric Service of the United States Army, and Commander Bracefield of the United States Navy. They have studied this program to date. They are permitted to recommend changes, if changes become desirable. We have developed what we consider to be the best possible system for the gathering of information of medical, social and educational histories on each registrant and have presented it in its present form for the aid of the psychiatrist at the induction stations. The Medical Survey Program has been set up in response to a request from the Secretary of War to General Hershey, saying that a system of assistance must be developed in this field. I would request that all who have to do with examinations utilize the material col-

lected to the utmost. The problem has been in effect only six months. Most of our difficulties have been surmounted. The program has advanced far beyond what I believed was possible for any program of this magnitude in the short time it has been in existence. If you have suggestions for change, make them to the committee referred to or to Dr. Waggoner. All suggestions will be given serious consideration. In the meantime, I believe that if you will use this plan you will find that it fills a real need. The system should become more valuable as time passes.

DR. RAYMOND W. WAGGONER, Ann Arbor, Mich.: There have been many difficulties with those who were charged with the execution of the program and quite as many difficulties among those charged with its use. Perhaps this is the most serious problem. Many of us may feel that it is evidence of our inability to do a good job to have to rely on assistance such as that furnished by the Medical Survey Program. No one can deny that a good medical-social history is of great importance in making a prognostication concerning the future mental health of the individual. A question has just been handed in asking whether there are any data as to how we compare as a nation with respect to the occurrence of neuropsychiatric casualties with other nations, particularly Germany and Italy. I am not in possession of information necessary to answer the question.

PSYCHOSOMATIC RELATIONSHIP TO GASTROINTESTINAL DISEASES

MARTIN G. VORHAUS, M D.

AND

S. ZACHARY ORGEL, M.D.

NEW YORK

The early twentieth century witnessed the ascendancy of the therapeutic nihilism of Osler. It had been preceded and influenced by a structural concept of disease derived from the precise pathologic investigations of Virchow. These autopsy studies had stressed abnormal cellular findings and centered the activity of medical students in the morgue.

The rebellion from the concept that disease is a fixed pathologic state was led by the modern psychologists. Their investigations of the psyche emphasized the role of the personality in the expression of disease. It is largely the result of these studies that has terminated the independent development of internal medicine and clinical psychiatry. No longer should a patient be treated only in terms of his specific complaints. A careful survey is made of the sick man from the standpoint of his personality as well as his organic disturbances. This new approach, which has as its basis the recognition and acceptance of the interdependence of the psyche and the soma, is known as psychosomatics.

The gastrointestinal tract is the primary battleground for the conflicts between the psyche and the soma. Here is the site for many primitive gratifications and abuses, adjustments and accommodations. These concepts have long been recognized but are only now being translated into a dynamic plan of treatment. Until now the results in the treatment of the functional disorders of the gastrointestinal tract have been largely unsatisfactory. Since these so-called functional cases represent more than a majority of all those seen in a gastrointestinal clinic or in private practice, the large percentage of failures in this group is a challenge. To meet this challenge the gastroenterologist must approach the psychotherapeutic problem with the same precise skill that he employs in establishing a physical diagnosis.

Our purpose in this paper is to correlate and emphasize clinical experience dealing with:

1. The recognition of the origins and mechanisms of some gastrointestinal symptoms.
2. The exposition of basic principles of psychosomatic therapy.

In our studies we have arbitrarily divided our patients into two categories. The first group consists of those in whom no organic gastrointestinal disease can be demonstrated. Various clinics¹ have estimated that this so-called functional group represents from 50 to 75 per cent of all patients. The second group consists of those patients with true organic disease in whom concomitant psychologic disturbances complicate, mask or interfere with the treatment of their organic disease. No accurate estimate has been made of the percentage this group represents.

Irrespective of the type of case, it becomes essential to investigate not only the physical components but the psychosomatic factors as well. The first step in this direction, which is best taken after the diagnosis of physical disease has been established or proved absent, is the taking of the psychosomatic history.

PSYCHOSOMATIC HISTORY AND DIAGNOSIS

The fundamental cause of psychosomatic illness is the emotional immaturity of the adult. It is this lack of emotional stability that occasions the conflict between the intellect and the emotions, which in turn creates the disharmony conducive to ill health. By treating the individual and not his gastrointestinal tract, the physician will attempt the reeducation of the emotions which is the psychotherapeutic goal.

Felix Deutsch² and others have stressed the skilful guiding of the patient's discussion of himself as a medical case and as a human being. The physician must give the patient sufficient time to tell his story in his own way. Two important objectives are thus gained: first, the cathartic value to the patient by the recitation of his difficulties and, second, the establishment of the patient's confidence through the demonstration of sincere interest by the physician. The ideal method seems to be one of casual conversation, utilizing free association and careful questioning. Only as the physician gains the patient's confidence can he learn of the past struggles and the conscious present anxieties of the patient's life situation in regard to family, friends and business.

Dumbar³ suggests that the following important diagnostic points be obtained from the history: 1. "A picture of the patient's life in which his major environmental stresses are outlined, together with his psychological and physiological reaction to them." 2. A picture of the patient's characteristic reaction pattern in terms of the environment and emotional situation to which he has adjusted with ease or difficulty, again in relation to illness history. 3. The topics he tends to avoid and misrepresent, and the topics that are accompanied by an increase or decrease in his skeletal or vegetative response and by temporary increase or relief of his symptoms. Type of defense used by the patient—whether he will try to keep his anxieties to himself or seek relief in action, as for example fidgeting or walking

up and down the room, or seek relief in smoking or talking about his symptoms. Attention should be paid to hesitancy, crying, laughing, evasion, tenseness and an increase or decrease of symptoms. 4. Dreams and other indications of the unconscious, especially divergences between dream material and the patient's statements may be of value. This presumes adequate special training on the part of the physician in the interpretation of this material.

The review of the psychosomatic history should enable the physician to make a diagnosis of the personality disorder. The psychopathologic basis of the specific personality disorder then becomes clear and permits an exact diagnostic term. This will be one of the accepted classifications of psychoneuroses or psychoses or some combination of them.

PSYCHOSOMATIC THERAPY

In the first group of cases in which the diagnosis "no organic disease" has already been made, psychosomatic therapy should be instituted early. It should be reemphasized that all steps should have been completed to eliminate the possibility of physical disease before psychotherapy is begun. Group 1 has been subdivided into (a) mild, (b) moderate and (c) severe. In group 1a (mild), if the symptoms are of short duration, simple reassurance may suffice to effect a cure. Often, if the intelligence of the patient permits, superficial insight is extremely helpful.

CASE 1.—A married woman aged 35 with abdominal discomfort and low abdominal pain of three months' duration was asked to face the fact that there was no organic disease present. Investigation into the personal history disclosed a sense of guilt due to an extramarital relationship. The resulting tensions created a psychogenic stimulus for her gastrointestinal symptoms. Her recognition of her anxiety as a causative factor of her complaints was followed by disappearance of her symptoms. The essential fact to be recognized in these cases of mild anxiety is the value of mental catharsis. Often simple encouragement to the patient to talk out his present day problems is followed by relief of his tensions.

In cases of moderate severity and longer duration, group 1b (moderate), reassurance alone is often insufficient. In this group it is necessary to plan and carry out a program of education for the patient. The first step is to awaken a recognition that the gastrointestinal symptoms are simply a geographic transfer of emotional tensions. The object of this educational program is to assist the patient in "calling things by their right names." The sooner the patient is able to recognize that the origin of his discomfort is psychologic the quicker will his insight develop. In this process of education the clinician should keep in mind the experience of the psychiatrist who has demonstrated that often the patient will not readily accept from the physician any explanation of psychologic mechanisms. On the other hand, those conclusions laboriously and circuitously arrived at by the patient himself have greater validity and are productive of more insight. In effect, the psychotherapeutic approach stimulates the patient to discover his own transference of tensions. The physician then repeats the patient's words, approving and agreeing with his discovery. The statement by the patient is no assurance that the thought expressed has reached the conscious level. The repetition of the same words by the physician now becomes a conscious thought, since it reaches through the auditory mechanism into the conscious awareness of the patient, coming to him from a parent ideal or substitute. This approval

is accepted with gratitude, or, as the psychiatrist says, "The patient feels that he is getting love." The usual result of this situation is a further stimulation of the patient to reveal more of his hidden tensions and thus gain further insight. This learning process is often slow and halting, especially when resistance of the patient is pronounced. In such instances the use of repetition of essential points is of considerable value. The capacity to learn varies with patients. Some learn quickly, others slowly, and many tend to suppress all or part of what they have recently learned.

CASE 2.—The case of a man aged 25 with a history of low abdominal pain and bouts of diarrhea of eight years' duration serves to illustrate these points. A diagnosis of colitis had been corroborated by several physicians and accepted by his draft board as sufficiently valid to classify him as 4-F. After a physical examination, sigmoidoscopic studies and gastrointestinal x-ray examinations had failed to reveal any organic disease, investigation of his personality disclosed a clearcut feeling of inferiority. For many years a constant fear of failure arose from any type of competition in school or in his job and from his social contacts with his contemporaries, both male and female. The diagnosis was revised to one of irritable colon with psychosomatic factors. In succeeding sessions he was encouraged by free association to describe those events associated with the onset of individual attacks. After reliving several of these experiences, the importance of his fear in the production of an attack became apparent to him. It was not long thereafter that he asked the question "Does fear bring on these attacks?" This stimulated further discussions concerning the origin of his fears and the psychologic meaning of diarrhea. Clinical improvement became apparent with the comprehension of his fears and their effects. This patient has been under observation for two years. In the two mild recurrences of diarrhea that have brought him back for observation he was able to state without prodding the entire sequence of events from dread of failure to diarrhea.

In the 1c (severe) group we have placed those patients whose symptoms are sufficiently serious to produce considerable interference with the normal routine of life. Many of these patients are unable to carry on adequately in their jobs. Frequently the complaints have existed for more than half the life span of the patients. Because of the long duration of symptoms considerable difficulty is encountered in obtaining an accurate psychosomatic history. Greater skill is required in eliciting the personality problems, many of which extend thirty or more years back into childhood. This longer period of time has created greater facility for complicated displacements of emotional tensions; the trail from these to the geographic transfer in the gastrointestinal tract is often vague. The patient's resistance to the psychosomatic approach should be anticipated by the clinician. Few if any ideas are willingly accepted and are rarely self learned. The inability to accept the significance of symbolism predominates. The experienced practitioner of psychosomatic therapy soon learns the expected limitations of treatment with this group of patients. To him they are the equivalent of the chronic cardiac, chronic bronchiectatic and the chronic nephritic so often encountered in internal medicine. Since resistance to therapy is strong and the pattern of tension complicated, the gastroenterologist must screen this group with a view to separating those patients sufficiently young and malleable for psychoanalytic therapy. For the remainder, into which group most of the older age patients fall, the only plan is "to carry on." In this technic of "carrying on," constant reassurance is the main "crutch" offered to the patient. It should never be

the only means of support. Even here the physician should encourage the patient at each session to discuss concerns other than the gastrointestinal complaints. Repeated efforts should be made to direct these energies and tensions into some creative or otherwise productive field of endeavor. In this connection the stimulation of avocations and the development of hobbies as a form of occupational therapy is of inestimable benefit. Their value is to direct the patient's thoughts of his own and his family's concerns into other channels. By this projection the patient derives not only relief from his own tensions but satisfaction in his new hobbies.

CASE 3.—A woman aged 61, with over forty years of belching, will serve to demonstrate some of these mechanisms. Since adolescence, repeated and often audible eructations of gas had driven her from doctor to doctor. In the last twenty years the additional story of a substernal lump soon after swallowing and the existence of transient cardiospasm required repeated medical investigation. The usual studies, a survey which required much less time and effort than the attempts at taking a psychosomatic history, excluded any organic disease. She was first of all persuaded to give up all medications previously prescribed. After repeated attempts, her interest in her symptoms was diverted and directed into her personal problems. Believing that some clue to the beginnings of her illness might become apparent, she was encouraged to talk of her childhood. In one of these sessions she mentioned a long cherished hope of learning to paint. The assurance that she was neither too old nor too ill to take up this hobby was grasped as the first constructive concept in many years. For the past ten years all of her free time has been spent in this pursuit. It is now six years since the last attack of cardiospasm, and her aerophagia reappeared only at the eve of her "one man show," given this season at the age of 70.

Typical case histories as the three quoted tend to oversimplify the problems of psychosomatic therapy. This faulty perspective has been created by the deliberate selection of cases, as each one of them was chosen to illustrate different phases of this group. Whenever the physician is dealing with patients whose symptoms arise solely from psychosomatic factors, the absence of organic disease is a potent ally. At moments of despair, at the end of a blind alley, the encouragement to be derived from the constant reiteration that "You have no organic disease" often enables the patients to take their first step forward on the path to health.

In the treatment of group 2, those with organic disease plus psychosomatic factors, a totally different situation exists. The patient must face and the physician must freely admit the existence of physical disease. To this burden is added the need for recognition and acceptance of a complicating psychologic disturbance. Since it is only rarely that the two states can be concurrently treated, and since priority must be granted to the therapy of the organic disease, this state of affairs is a deterrent to the onset of psychosomatic therapy. Much time and effort is spent with this group of patients, outlining the steps to be taken for improvement and possible cure. In many instances detailed explanations are required as to which symptoms arise from organic disease and which from emotional stresses. Often these have an intricate interrelationship, and for most of these patients an early acceptance of the role of the psyche and the soma is impossible.

CASE 4.—An illustrative case in the 2a (mild) group is that of a man aged 39 complaining of attacks of dull epigastric discomfort, belching and nausea for over ten years. The patient had observed these attacks carefully and knew that certain foods and emotional strain were competent producing causes of these attacks. The physical factor was a dilated, poorly

functioning gallbladder without demonstrable stones. The emotional factors centered about a closely knit excitable family in which the patient and his youngish stepmother were the hub of neurotic stress. In the plan of treatment it required but little time for the patient to recognize his difficulties with his stepmother, but he had very little insight into the incestuous nature of his drive. His economic level precluded psychoanalytic treatment. In the course of time he gradually permitted himself to seek companionship out of the home. This loosening of the familial ties was followed by increasing interest in female companionship, which culminated in a happy marriage and his attacks abated. Family reunions, especially at holiday times, are usually followed by a mild recurrence of symptoms, but these are of short duration. In the last six years he has been free from anxiety in regard to his health and relates frankly and with some amusement of the family friction that precipitates each attack.

The cases of moderate severity (2b) present greater difficulties in treatment, and yet even here the results need not be too discouraging.

CASE 5.—A case in point is that of a 19 year old youth discharged from the Navy after eight months of service with a diagnosis of duodenal ulcer as his medical disability. For five years symptoms had been present, and the diagnosis had been established and confirmed. The personal history disclosed the fact that the year before the onset of his symptoms his father had died, following an operation for duodenal ulcer. The patient, an only child, left school and assisted his mother in a small retail business, which was the sole source of income for the family. The conflicts between mother and son occurred daily, both at work and in the home. Since the educational and economic level of the patient placed psychoanalytic therapy beyond his reach, the more superficial psychotherapeutic approach was attempted. As the duodenal ulcer responded to treatment, the patient discovered that his Sundays, if spent outdoors, were his most comfortable times; he was encouraged to take more physical activity. After his symptoms abated and the x-ray follow-up substantiated this improvement, he was urged to translate his love of the outdoors, and separation from his mother, into a plan for future vocation. With the aid of a scholarship he is now learning agriculture at a farm school, and his freedom from symptoms and gain of 15 pounds (6.8 Kg.) in weight provide a real promise for the future and permit a temporary classification of a successful therapeutic response.

In the last category, 2c (severe), fall the most difficult problems. Most of these patients are past 40, and their enjoyment of life has been impaired by their illnesses for many years. The physical disease is usually incurable, and the groove of psychogenic tension is often ineradicable.

CASE 6.—The case of a woman aged 64 with rheumatic heart disease, mitral and aortic insufficiency and a complicating hiatus hernia will serve to demonstrate this group. When first seen she was in mild congestive failure, which responded to the usual treatment. Her heart disease had been known to her for many years, and she had made a good adjustment to it. X-ray studies revealed a hiatus hernia, which explained her more recent attacks of high epigastric pain and its associated symptoms. To accept this additional physical disease was more than she was willing to bear, and her first reaction was to deny its existence. After corroboration of the diagnosis at other clinics, she reluctantly and even resentfully accepted the need for treatment. It was at this point that a satisfactory psychosomatic history was first obtained. Investigation of her emotional tensions revealed an involved interlinking of her gastric symptoms with her wish for self punishment and her death drive. As was to be anticipated, little headway was made in the early weeks of treatment. Slowly she began to realize that these repeated aggressive attacks had not resulted in the death that she anticipated. Gradually it became apparent that these episodes occurred only in the presence of loved ones or in public places and produced painful embarrassment. In

effect the gastric symptoms symbolized her willingness to give and her unconscious desire to receive the love and help of her dear ones. It was possible at this time to institute sufficient psychosomatic therapy to disassociate her anxieties from her gastric symptoms. She gradually attained sufficient superficial insight to provide her with the courage to meet her emotional problems without creating the mechanism of geographic transfer. In the past four years her complaints have been less frequent and less intense. The symptoms of her hiatus hernia continue, but they are no longer initiated or aggravated by her emotional tensions.

In the presentation of this clinical study it is a relatively simple task to divide arbitrarily all cases into the two groups mentioned—i. e. functional and organic. In actual practice there is in addition a small number of patients who appear to fit into an intermediary group. These patients at first manifest symptoms which arise only from functional disturbances, but after a lapse of time there develops real organic disease. This type of case is not only seen in a gastrointestinal clinic. Many internists believe that toxic diffuse goiter and essential hypertension may well fit into this group, which many of us classify as the "dynamic diseases." Schematically it can be represented as psychologic disturbance, alteration in secretory and/or motor activity, diminished cellular vitality, organic disease. In this group may be included cases with mucosal ulcerations in the esophagus, stomach, duodenum and colon. Also patients with disturbances of sphincteric control (namely, cardiospasm, pylorospasm, sphincter of Oddi spasm, anal sphincter spasm or relaxation) may well fit into this transitional group. To what extent a functional disturbance in the mechanism of the sphincter of Oddi can eventuate in organic disease of the gallbladder and/or the pancreas may at the moment be left for future speculation.

UNITY OF THE PSYCHE AND THE SOMA

The ancient belief that sickness is a visitation from the Lord, a punishment for evil, still persists in the mind of man. Although scientific advances have stamped this as superstition, we know that every man creates and obeys his own god or gods and that every man decrees and executes judgments of punishment on himself. For some it is necessary to have a daily stint of punishment and pain; at times an external cross is replaced with an internal one, such as an organic disease. Observations such as these have encouraged modern medicine to investigate the influence of psychic factors on physiologic functions. The physician of the prescientific period was concerned with the entire life situation of his patient. The exact laboratory methods of the latter part of the nineteenth century reduced the psychic theory of disease to superstition, but recently the importance of the psychic status of the patient is again receiving attention. This interest has been stimulated by the work of Freud and Breuer and their students, who clarified many personality disorders and elaborated the libido theme and ego and character analysis. This resulted in an understanding of the role of the emotional factors in illness complicated by or eventuating in actual organic damage. Interest then gradually veered to a study of symptoms produced by disturbances in the autonomic nervous system and led to what Freud termed the "future of medicine." This was the investigation of the psychogenesis of those organic disorders theretofore segregated from psychiatric interest because of their supposed organic causation.

Alkan⁴ stated in 1930 that organic disease may be profitably studied by psychologic methods. He indicated that psychogenic disturbances within the field of the autonomic nervous system may result finally in organic changes whose morphologic mechanisms form only the last link of an intricate causal chain. He postulated that intrapsychic conflicts may be expressed by spasms of smooth muscle which secondarily lead to anemia of an organ, vascular stasis, dyskinesia, atrophy or infection. The result may be organic changes in visceral tissues or somatic structures, which of themselves, as terminal events, are irreversible and constitute the so-called organic disease.

Alexander and his group through their psychoanalytic researches have become convinced of the psychogenesis of gastrointestinal disorders. They believe that organic changes are the last link in a complicated functional chain of events of which the basic etiologic factors are psychologic conflicts. Alexander states that no disturbance of innervation of an organ could symbolically express a specific fantasy or a repressed idea. An organ's specific function, he believes, could be used to express a tendency of psychic direction which by a process of conflict could not normally be expressed through the voluntary nervous system and its organs of expression. To quote Alexander:

Physiologically the process of life can well be described in terms of the three major functions of *in-taking* of substances and energy from the environment, partially *retaining* it during the process of growth and *elimination*—elimination of the end-products of metabolism, elimination of substance for the purpose of propagation and the constant production of thermic and mechanical energy. It would not be surprising at all if it should turn out that the elementary psychologic tendencies of the individual correspond to these three biologic phases of life and that psychologic dynamics . . . correspond to the biologic dynamics of life.

Alexander⁵ and his group at the Chicago Institute of Psychoanalysis are impressed with the constancy and similarity between the nature of the psychologic conflict and the type of gastrointestinal disorder. They find it possible to describe the patient's emotional trends in terms of the three elemental tendencies applicable to both the psychologic conflict and the gastrointestinal symptoms. First, the wish to receive or take as related to gastric disorders; second, the wish to give or eliminate as applied to the diarrhea cases, and, third, the wish to retain as applied to the constipation cases.

Psychoanalytic theory explains why the functions of nutrition are especially adapted to express the repressed or externally thwarted receptive tendencies which we find predominantly in gastrointestinal disorders. In the psychologic development of the infant, his first interest and aim in life is concerned with the intake of nourishment. "The infantile wish to receive, to be taken care of, to be loved, to depend upon some one else, is most ideally gratified in the parasitic situation of the suckling infant. Thus these emotional qualities of receptivity become closely associated in an early period of life with the physiologic functions of nutrition."⁵ Being fed becomes the equivalent of being loved. The character attributes of the adult individuals with gastric disorders were often found to be ambition and aggressiveness. They consistently strove to be independent, active and efficient, and frequently had

4. Alkan, L.: *Anatomische Organkrankheiten aus seelischer Ursache*. Stuttgart, Hippokrates Verlag, 1930.
5. Alexander, F.: *Psychoanalyst Quart* 2: 501, 1934.

achieved considerable success. The unconscious desires of these individuals, however, showed that this desire for independence, ambition and self assertiveness was an overcompensation. They were leaning over backward to repress or deny completely their unconscious wish to be dependent, to be loved, to be fed. It was thus apparent that in these gastric neuroses the unconscious desire in the primitive mind was directly associated with the child's first manifestation of love, namely food and nourishment. It is presumed that the gastric symptoms are caused through these unconscious tendencies which serve as chronic psychic stimuli to the stomach, independent of the process of nutrition. The stomach behaves as if it were taking or about to take food. The greater the rejection of every receptive gratification in life, the greater will be his unconscious wish for receiving love and help. Food is craved not because of organic hunger but as a symbol of love and help. The stomach under this permanent chronic stimulation constantly behaves as if it were about to receive food, or as during digestion. The epigastric distress, heartburn, belching and other symptoms of the nervous stomach are probably due to this chronic stimulation and provide one theory for the development of ulcer.

Many patients with irritable colons were found to solve the same conflict in a different yet typical manner. "The dynamic formula for these cases is as follows: 'I have the right to take and demand, for I always give sufficiently. I do not need to feel inferior or guilty for my desire to receive and take, because I am giving something in exchange for it.' The assumption is that the diarrhea apart from expressing aggression serves as a substitute for giving of real value."⁸ In this conscious attitude there is again apparent the parallelism between the nature of the disorder, namely diarrhea, and the person's attitude toward life, particularly as it is reflected in his relations with other people.

It is easy to understand why the lower end of the intestinal tract is especially suited to express activity, aggression and the wish to give. Here, as in the gastric cases, it is assumed that the peristaltic function of the intestine under the permanent psychic stimulus of the wish to eject and to give becomes independent of the normal physiologic regulations. This explanation stems from psychoanalytic findings which link the early coprophilic attitude of the child with the unconscious symbolic significance of the intestinal contents as a valuable possession. The use of defecation as a sadistic or an aggressive tendency develops after the child learns to assume a deprecatory negative attitude toward his excremental function.

In the analytic study of some patients suffering from constipation, the individual's emotional attitude toward his environment can be expressed in terms that apply equally well to his psychologic problem—namely, to retain or to hold on. The conscious attitude in these individuals demonstrates an unwillingness to receive help from others or to depend on them. At the same time there exists an extreme sense of obligation to give, of which the patient tries to rid himself by renouncing all conscious tendencies to receive. The conscious attitude is summarized as "I do not take or receive; therefore I do not need to give." Added to the positive evaluation of the intestinal content as a valuable possession is found an anal-sadistic attitude, the inhibition of which contributes to constipation.

The findings of the psychiatrists in these three groups are significant, but the dynamic tensions of all patients cannot be reduced to these three types of gastrointestinal disorders. In many individuals there exists a specificity of unconscious demands, and the gastrointestinal tract is often affected by these chronic psychogenic stimuli. Psychoanalytic treatment offers the possibility of adequate knowledge of these factors—not only to the psychiatrist but to the patient. When psychoanalysis cannot be instituted, a study of the life situation of the patient and insight into his repressed tendencies and unconscious desires will reward the internist trained in psychosomatics with a clear understanding of the therapeutic problem.

SUMMARY

The psychosomatic approach has a special value in the treatment of the functional gastrointestinal patient. The high percentage of therapeutic failures hitherto encountered in this group is largely due to a lack of recognition of the psychobiologic disturbances. To meet this problem satisfactorily the gastroenterologist must be as thoroughly trained in psychosomatics as he has been in internal medical diagnosis and treatment. The acceptance of the unity of the psyche and the soma is an essential of the psychosomatic concept. A primary requisite toward the establishment of an accurate psychosomatic diagnosis is the method of taking the psychosomatic history.

Careful screening of all patients and the selection of those suitable for psychoanalytic therapy is an obligatory function of the internist. For the remainder, the gastroenterologist must render as much psychotherapy as the flexibility and intelligence of the patient permit.

In those cases in which psychologic disturbances are coexistent with organic disease, the utilization of psychotherapy in conjunction with medical therapy is of value.

The modern concept of psychosomatics reemphasizes the need for the treatment of the entire patient, his emotional difficulties as well as his physical disease.

In the future therapy of gastrointestinal diseases the psychosomatic approach will play a distinguished role.

1130 Park Avenue—667 Madison Avenue.

ABSTRACT OF DISCUSSION

DR. FRANZ G. ALEXANDER, Chicago: From the practical point of view, a differentiation between cases with and without organic disease is perhaps permissible. Theoretically the validity of such a sharp distinction is questionable. A more adequate distinction would be to differentiate between disturbances with and without irreversible structural changes. Also the subdivision into mild, moderate and severe cases is, from the practical point of view, permissible. Under the influence of traumatic experiences, mild cases may turn into moderate or severe cases. In the field of psychogenic disorders we must be aware of the extreme fluidity of such conditions. It is a well known observation that severe peptic ulcer symptoms may rapidly disappear when the patient is placed in a sanatorium, and then released from his daily emotional strains. Such an observation alone suffices to demonstrate the futility of any attempt to try to attach a diagnostic tag such as mild, moderate or severe to any case as a permanent description. The more experience one has with psychosomatic disturbances of the gastrointestinal tract, the more one becomes impressed with the

capriciousness both of symptomatology and of therapeutic results. The patient's intrinsic capacity to deal with his emotional problems, on the one hand, and the flexibility of the life situation, on the other, determine the therapeutic chances. A patient whose life situation does not allow changes which would relieve emotional tensions will react more slowly to therapeutic efforts. The capacity of such patients to deal with emotional tensions must be changed, which is always a much more difficult and time consuming therapeutic task than the adaptation of the life situation to the emotional needs. The evaluation of all the etiologically important factors requires expert knowledge both in the principles of psychodynamics and pathology and in the principles of clinical medicine. I agree with the authors' emphasis in requiring that the modern gastroenterologist should be equally equipped in all these fields. The novel feature in this emphasis is the requirement of acquaintance with the principles of psychodynamics. Knowledge of clinical medicine and pathology has been for a long time a standard requirement. The fact that at present we are able to evaluate the specific role of emotional factors in the diseases of the gastrointestinal tract makes it imperative that our psychotherapeutic approach should be specific and etiologically oriented. Many patients suffering from gastrointestinal disorders can be helped by a simple ventilation of their emotional conflicts or by reassurance and rest; however, the physician should know why in certain cases such simple methods suffice and others require prolonged psychotherapeutic treatment. Without a specific knowledge of psychodynamics, the psychotherapy will remain the old hit-or-miss variety of treatment.

DR. SIDNEY A. PORTIS, Chicago: Drs. Vorhaus and Orgel have presented an approach to a problem that confronts all of us who are doing serious thinking. I am always concerned, when looking at a patient from a psychosomatic point of view, that I am overlooking some organic disease, and I tell myself that first, last and always I am a physician, and the responsibility for any oversight lies in my hands. However, after a serious intensive investigation, when one confirms an original suspicion that the problems of a patient are entirely psychogenic in origin, it is up to the physician to outline adequate care. Many patients cannot afford prolonged psychotherapy; on the other hand, a fairly large number will have to have some psychotherapy. In order that the patient should have the medical treatment that is adequate to meet this problem, I have developed a regimen which in my own hands has yielded me the best results I have seen in over twenty-five years in gastroenterology. One of the most perplexing factors in the clinical pictures of these patients is the question of fatigue. Twenty-one months ago I began studying fatigue and came to the conclusion that it was probably associated with a disturbance of the carbohydrate metabolism which has its origin in a presumed hypersecretion of insulin. This was evidenced by the so-called flat curve which resulted when intravenous glucose tolerance tests were made. I found that these patients became hypoglycemic at the end of the two hour test. Therefore the therapeutic approach to this problem was to maintain the high level of blood sugars at all times. In order that the hyperirritable glands of the pancreas should not be stimulated too rapidly, free sugar in any form was noticeably omitted from the diet. The complex carbohydrates, proteins and moderate fat satisfy the demand for this relatively high sugar at all times. During the course of these observations the question arose Could it be possible that the early morning pain of a duodenal ulcer is associated with this relative hypoglycemia? Patients were given a small feeding before retiring. These patients got atropine three times a day and an additional dose at bedtime. They have been completely free from symptoms during the early morning hours, with no neutralization. In addition, the fatigue which was such an important part of the clinical picture had definitely disappeared. In observations and studies of over 450 patients with psychosomatic disease, which now covers a period of over twenty-one months, I was struck by the fact that the incidence of coronary occlusion was relatively nil. Also I was

impressed by the improvement in the electrocardiographic findings of the middle aged group when these patients were subjected to this fatigue management. And, while I have no clinical proof for the conclusions, it might be well for all of us to begin to think seriously that there may be some relation between myocardial damage and coronary occlusion and levels of blood sugar.

DR. BENJAMIN M. BERNSTEIN, Brooklyn: I don't think we need fear that we shall have to turn all our cases over to the neuropsychiatrists; as a matter of fact, we don't even have to learn psychiatric management, because you and I have been treating our patients psychologically. Have you ever tried to analyze what faith is? Why does a patient say "I went to an awfully good doctor the other day. He spent one full hour with me." She has faith. You have hypnotized her in the belief that you are going to cure her. Another patient says "I went to a wonderful doctor the other day. Why, in five seconds he knew what was wrong with me!" Faith again. That is psychotherapy. Knowing the type of individual as he comes into your office, seeing how he walks, how he stands, how he sits and how he sweats, if you will, give a clue as to the kind of individual you are dealing with. Of course, we all go wrong, at times. We see persons who have gallstones, who are operated on for gallstones, and they don't get well! We explain by saying biliary dyssynergia, biliary stasis, chronic pancreatitis—I don't believe it matters. I believe we are dealing with individuals who have a particular kind of constitution, who have abdominal symptoms, if you will, not necessarily gastroduodenal, based on causes that we know little or nothing about. You may give the same patient the same medication the other fellow gave. With a bit of "salve" and some common sense, and a pat on the back, you are doing psychotherapy. We all have to be psychotherapists. I am afraid sometimes we may have to throw most of our abdominal conditions into the field of trophopathic disorders, even gallstones perhaps, particularly cholesterol stones, certainly colitis, even though secondary infection plays an important role, and most importantly, of course, gastroduodenal dys-synergia.

DR. GEORGE B. EUSTERMANN, Rochester, Minn.: As so large a percentage of patients with gastrointestinal disorders harbor no demonstrable organic lesions, every gastroenterologist also should have neuropsychiatric training. A preponderance of psychoneurotic patients have as their presenting complaint disturbances of a gastrointestinal nature. Unlike Dr. Palmer, I am strongly of the opinion that gastroduodenal ulceration, in the large majority of cases, has its origin in physical, nervous or emotional stress, or a combination of these factors. We can no longer dismiss the neurotic patient with the cheerless statement that there is nothing wrong with him and prescribe a sedative as a routine measure. Of course the psychotherapeutic value of a thorough, even though negative, examination by a physician in whom the patient has every confidence is generally recognized. We have postponed too long doing for these unfortunate individuals what for years we have done systematically for arthritic and diabetic patients for example, namely group instruction and treatment by lecture, demonstration and personal interviews. This is being successfully done at our state university, as it has been done in various Eastern institutions for some years. Following the exclusion of any significant organic disorder by the internist, which includes the application of all modern approved methods of examination, the neuropsychiatrist then takes charge. Among other things, the emotional factor underlying the complaint is determined and the patient given an adequate insight into the mechanism which gives rise to his physical disturbances as the result of a personality disorder. Usually after six to eight weeks recovery follows unless the patient is actually psychotic, uncooperative or the victim of a deep seated systematized neurosis. Finally, one is always faced with the problem of the psychoneurotic patient who also harbors an organic lesion, duodenal ulcer in particular. Not infrequently it is essential to determine which condition is paramount, the neurosis or the ulcer. We have all had the somewhat embarrassing experience of successfully healing by treatment or

removing by gastric resection lesions of the digestive or biliary systems only to realize that cure was not effected and that the patient sooner or later continued to complain as volubly as before.

DR. S. ZACHARY ORGEL, New York: In psychosomatic disorders we are not interested in obtaining as many facts as possible but in getting information that has not been prepared for the occasion. Thus one learns how the symptoms develop and what the symptoms meant to the patient from early childhood. He is stimulated to give the information by having him describe his organic complaints without making him aware of a psychology background in his illness. He will give the material necessary for a proof of a psychosomatic unit in his illness only if he is not aware of what he reveals to us about his emotional life. The patient, if allowed to talk without being asked leading questions, will usually give a detailed account of his complaints and ideas about his illness. When he has exhausted his ideas and recollections about his organic disturbance, he will stop and wait to be questioned. After being certain he will not continue spontaneously, the examiner repeats one of the points of the patient's last sentence, in an interrogative form, care being taken to use the patient's words. New information centering around his symptoms is usually now stimulated. He drifts into giving a communication in which he inattentively mixes emotional and somatic material. References to persons in his environment, both from the present and from the past, then begin to appear. This usually is the beginning of a critical phase of the examination. Material will now appear which leads to the three essential points in establishing the psychosomatic unit: the old conflict, the recent conflict and the time factors. Persons first appearing are usually relevant from the psychosomatic point of view. Correlation of organic illness with the patient's emotional life now becomes evident. Thus we learn a great deal about the neurotic conflicts of these patients.

Clinical Notes, Suggestions and New Instruments

RETRO ORBITAL ADRENAL REST TUMOR

LEE W. HUGHES, M.D., AND ANTHONY AMBROSE, M.D.
NEWARK, N. J.

This case is being reported because of the apparent rarity of its occurrence. A search of the textbooks in ophthalmology at our disposal has failed to disclose a report of any such case. No doubt there have been others seen which probably were not reported.

The patient was a woman aged 21, whom we first saw March 21, 1944. Her past and present health had been good.

Fig. 1.—Tumor mass.

She had measles, pneumonia and mumps during childhood. Her chief complaint was that the left eye had been gradually protruding forward, downward and inward since February 1939. At that time she was struck over the left eye with a hard packed snowball. There was a sharp stinging pain in the eye. Cold compresses were applied and by the next morning the eye felt better. She stated that it never became discolored. She did not have any further trouble until early in 1941, when she noticed a slight swelling over the left eye, which appeared at

certain intervals. By the following year the swelling was more definite and she began to notice that the eyeball was protruding.

Examinations revealed that the vision in the right eye was 20/100, with correction 20/30; vision in the left eye was 20/70, with correction 20/30.

There was a moderate swelling of the left upper lid, especially in its outer two thirds. The eye was protruding downward,

slightly inward, and noticeably forward. The ocular motility was good; there was no diplopia. The condition was thought to be a hemangioma which resulted from the accident in 1939.

She was operated on under general anesthesia April 13, 1944, at the Newark Eye and Ear Infirmary. The external canthus was split directly outward to the edge of the orbit. The con-

Fig. 2.—Appearance before operation.

junctiva was open and dissected backward. The external rectus muscle was fixed with catgut and then severed near its insertion. Digital exploration of the retrobulbar space revealed the presence of a more or less olive shaped swelling behind and slightly above the globe. It seemed to be firmly fixed. A

Fig. 3.—After operation.

curved blunt pointed scissors was placed along the outer side of the bony orbit until the lateral border of the tumor was reached, and then with careful spreading of the blades the tumor was partially dislocated. The remainder of the dislocation was done with the small finger tip. There was surprisingly little bleeding. The conjunctiva was closed with interrupted silk

stitches. The external rectus was reattached. The skin was closed with interrupted black silk sutures. A pressure bandage was applied.

A section of the tumor was sent to Dr. Harrison S. Martland, who had the following to say after the examination:

"After examining a microscopic slide of the tumor removed from the orbit I am expressing the following opinions:

Fig. 4.—Section under low power.

"The tumor is well encapsulated and appears to be a benign tumor, in that there is absence of mitosis, hyperchromatism and other malignant features.

"The tumor is composed chiefly of cells which appear like liver cells or cells from the adrenal cortex, and these are arranged in a manner similar to zona fasciculata of the adrenal cortex, occasionally showing lumen formation.

"There are many areas of small round cells.

"I am inclined to interpret the tumor as a congenital fault somewhat in the nature of an adrenal rest (which has been

Fig. 5.—Section under high power.

described in the region of the head) and am apt to regard the collections of small round cells as probably of neurogenic origin."

Postoperatively the patient made an uneventful recovery. There was only a slight diplopia when looking to the extreme right, which disappeared within a few weeks.

965 Broad Street—31 Lincoln Park.

CONTINUOUS INTRAMUSCULAR INFUSION OF PENICILLIN

FRANKLIN I. HARRIS, M.D., SAN FRANCISCO

The methods of administering penicillin described in the current literature are (1) continuous intravenous infusion, (2) repeated intramuscular injections and (3) topical application. In none of this voluminous literature have I been able to find any description or recommendation for giving this valuable drug by continuous intramuscular infusion.

Continuous intravenous infusion is objectionable because of the special and constant nursing care required; the occasional formation of thrombophlebitis at the site of injection and finally the constrained position of the patient's arm for twenty-four hours a day limits his activity and comfort.

Repeated intramuscular injections of penicillin are disturbing and painful and often prevent a patient from receiving a sufficient amount of rest in a twenty-four hour period. The nursing care is likewise increased.

As penicillin became available to civilian hospitals in greater amounts, our two surgical residents Drs. Walter Left and Lewis Karp suggested that we give penicillin to the patients in the surgical service by continuous intramuscular clysis. This suggestion was immediately accepted and since May 15, 1944 has been the method of choice for the administration of penicillin at the Mount Zion Hospital, San Francisco.

TECHNIC

The contemplated total dose of penicillin for twenty-four hours is dissolved in 1,000 cc. of sterile solution, exactly as in the preparation for continuous intravenous infusion. This solution is then allowed to run in by a drip method as an intramuscular clysis. One or both thighs may be utilized. The regular intramuscular clysis needles are used, and the outer or inner side of the thighs is the favorite site of administration as in any other type of intramuscular clysis. The usual rate of flow when 100,000 units has been dissolved in 1,000 cc. of saline solution is between twelve and fifteen drops per minute, which gives approximately 50 cc. per hour or about 5,000 units per hour. This rate of flow can be easily increased to give 10,000 units per hour or any desired dose. Many variations can be easily arranged. If more fluid intake is desired, the 100,000 units can be dissolved in two flasks of 1,000 cc. each.

This method requires no special nursing care, once the needle is inserted intramuscularly and the rate of flow established. The patient does not need close observation from this standpoint. Lately we have found it more advantageous to place the needle only in one leg. This permits the patient greater activity and movement in bed.

In the majority of cases we have averaged about 5,000 units per hour by intramuscular infusion throughout the twenty-four hour period. Our laboratories have not at the present time found it possible to determine the blood level and concentration of penicillin, but those of us who have used this method of administration believe that the penicillin effect is probably more evenly distributed and kept at a better level than by the repeated intramuscular injection. Further studies will have to be made in the future of the blood levels that are obtained by this method.

The clinical results with the continuous intramuscular method of administering penicillin have been eminently satisfactory in approximately 25 cases in which this method has been used from May 15 to August 1. There have been no complications, no abscess formation and no nursing difficulty that could be attributed to this method of administration.

This short note is submitted because it is believed that sufficient publicity has not been given to this safe and valuable method of administering penicillin.

SUBACUTE BACTERIAL ENDOCARDITIS TREATED
WITH PENICILLIN

B. C. COLLINS, M.D., MEMPHIS, TENN.

B. W. H., a white boy aged 10 years, was admitted to the Methodist Hospital Oct. 2, 1943 with a history of fever for the preceding four days and complaining of pain in the left lower chest, anorexia and general malaise.

X-ray examination at this time revealed a lobar pneumonia of the left lower lobe, infiltration of both hilar regions and slight enlargement of the heart, but no abnormality in contour.

Physical examination revealed an acute inflammation of the tonsils and tonsillar pillars. There was bronchial breathing and moderate dullness over the left lower lobe. Examination of the heart revealed a palpable thrill, a very loud blowing systolic and a subdued diastolic murmur about 2 centimeters to the right of the mitral area. These murmurs were not transmitted to the axilla or posteriorly. A tentative diagnosis of lobar pneumonia and congenital heart disease was made.

Laboratory studies showed 54 per cent hemoglobin, 2,950,000 red blood cells and 12,250 white blood cells, with a differential count of 76 per cent neutrophils, 23 per cent lymphocytes and 1 per cent large mononuclears. Urinalysis was negative. The corrected sedimentation rate by the Wintrobe method was 30 mm. in one hour.

Treatment consisted of one 300 cc. blood transfusion, sulfadiazine 1 Gm. immediately and 0.5 Gm. every six hours for two days, then 0.5 Gm. every twelve hours. The blood con-

Clinical course. S, sulfamerazine; P, penicillin.

centration was 12.9 mg. per hundred cubic centimeters on the second day of therapy. The clinical course was very satisfactory, the temperature returning to normal in seventy-two hours. The patient was discharged home on the ninth day, apparently cured.

The patient returned to the hospital on Feb. 9, 1944 with a fever of 104.2 F. A blood culture positive for *Streptococcus viridans* was obtained. X-ray examination at this time revealed an atypical lobar pneumonia of the right base. There was prompt and satisfactory response to sulfamerazine, 1.5 Gm. immediately and 0.5 Gm. every six hours for six days. The temperature dropped to normal on the second day of treatment but became elevated again four days after the drug was discontinued.

Blood cultures positive for *Streptococcus viridans* were obtained on February 11 and 29, March 22, 27 and 29 and April 6.

The patient received another course of sulfamerazine from March 6 to March 16 with little improvement, as shown in the accompanying chart.

Treatment with penicillin was started on March 31. The dosage was 100,000 Oxford units daily divided into eight equal parts and given every three hours intramuscularly. The total given was 1,400,000 units over a period of fourteen days. The response was rapid and very dramatic, the temperature dropping to 99 F. on the second day of treatment and becoming normal the following day. Negative blood cultures were obtained on April 8, 10, 12, 14, 16, 17, 19 and 24. The clinical improvement was excellent and on September 16 the patient was still afebrile and symptom free.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

GEORGE K. ANDERSON, M.D., Secretary.

PREPARATIONS USED IN THE FEEDING OF
INFANTS (See Accepted Foods, 1939, p. 156).

Harold H. Clapp, Inc., Rochester, N. Y.

CLAPP'S (BABY FOODS) CUSTARD PUDDING.

Analysis (submitted by manufacturer).—Total solids 21.86%, fat (by acid hydrolysis) 2.73%, protein (N \times 6.25) 3.06%, ash 0.62%, crude fiber 0.006%, carbohydrates (by difference) 15.44%, calcium (Ca) 137.09 mg. per hundred grams, phosphorus (P) 92.72 mg. per hundred grams, iron (Fe) 0.5 mg. per hundred grams.

Calories.—0.99 per gram; 28.1 per ounce.

Vitamins.—Vitamin A (carotene) 156 U. S. P. units per hundred grams.

Vitamin B₁ (thiamine) 0.03 mg. per hundred grams.

Vitamin C (ascorbic acid) 0.34 mg. per hundred grams.

Vitamin G (riboflavin) 0.38 mg. per hundred grams.

Harold H. Clapp, Inc., Rochester, N. Y.

CLAPP'S STRAINED PEACHES.

Analysis (submitted by manufacturer).—Total solids 14.53%, protein (N \times 6.25) 0.43%, ash 0.37%, crude fiber 0.09%, fat (ether extract) 0.06%, carbohydrates (by difference) 13.58%, phosphorus (P) 16.6 mg. per hundred grams, calcium (Ca) 4.8 mg. per hundred grams, iron (Fe) 0.37 mg. per hundred grams, copper (Cu) 0.10 mg. per hundred grams.

Calories.—0.57 per gram; 16.2 per ounce.

Vitamins.—Vitamin A (carotene) 169 U. S. P. units per hundred grams.

Vitamin B₁ (thiamine) 0.02 mg. per hundred grams.

Vitamin C (ascorbic acid) 2.0 mg. per hundred grams.

Vitamin G (riboflavin) 0.3 mg. per hundred grams.

Harold H. Clapp, Inc., Rochester, N. Y.

CLAPP'S STRAINED PEARS.

Analysis (submitted by manufacturer).—Total solids 15.61%, crude fiber 1.02%, protein (N \times 6.25) 0.56%, ash 0.21%, fat (ether extract) 0.08%, carbohydrates (by difference) 13.74%, phosphorus (P) 14.2 mg. per hundred grams, calcium (Ca) 8.5 mg. per hundred grams, iron (Fe) 0.69 mg. per hundred grams, copper (Cu) 0.09 mg. per hundred grams.

Calories.—0.58 per gram; 16.5 per ounce.

Vitamins.—Vitamin C (ascorbic acid) 0.74 mg. per hundred grams.

Vitamin G (riboflavin) 0.03 mg. per hundred grams.

Gerber Products Company, Fremont, Mich.

GERBER'S CHOPPED VEGETABLE AND LAMB WITH BARLEY, consisting of potatoes, water, carrots, lamb, green beans, pearl barley, barley flour, onion powder and salt.

Analysis (submitted by manufacturer).—Moisture 86.8%, ash 1.2%, fat 2.2%, protein 2.4%, crude fiber 0.4%, carbohydrates (by difference) 7.0%, Ca 0.010%, P 0.040%, Fe 0.0009%, Cu (?)?

Calories.—0.6 per gram; 16 per ounce.

Vitamins.—Protocols of assay (1941) show that this product contains 900 international units of vitamin A, 0.032 mg. of thiamine and 2.3 mg. of ascorbic acid for each hundred grams.

Gerber Products Company, Fremont, Mich.

GERBER'S CHOPPED VEGETABLE AND LIVER WITH RICE, consisting of potatoes, water, celery, tomato pulp, beef liver, carrots, rice, salt and onion powder.

Analysis (submitted by manufacturer).—Moisture 88.7%, ash 1.3%, fat 0.3%, protein (N \times 6.25) 2.6%, crude fiber 0.3%, carbohydrates (by difference) 6.9%, Ca 0.015%, P 0.044%, Fe 0.0013%, Cu 0.00031%.

Calories.—0.4 per gram; 12 per ounce.

Vitamins.—Protocols of assay (1941) show that this product contains 8,100 international units of vitamin A, 0.074 mg. of thiamine and 1.5 mg. of ascorbic acid for each hundred grams.

Gerber Products Company, Fremont, Mich.

GERBER'S PINEAPPLE-RICE PUDDING (JUNIOR FOODS).

Analysis (submitted by manufacturer).—Moisture 74.36%, ash 0.85%, fat 0.62%, protein (N \times 6.25) 1.67%, crude fiber 0.20%, carbohydrates (by difference) 22.30%, calcium 0.0416%, phosphorus 0.0378%, iron 0.00085%, copper 0.00004%.

Calories.—1.02 per gram; 29 per ounce.

Vitamins.—Carotene, 0.0135 mg. per hundred grams.

Thiamine, 0.034 mg. per hundred grams.

Ascorbic acid, 0.78 mg. per hundred grams.

POSTWAR TRAINING FOR RETURNING OFFICERS

Elsewhere in this issue is a preliminary estimate, prepared by the Council on Medical Education and Hospitals, of the probable demand for advanced graduate training by returning medical officers. The report suggests ways in which efforts may be applied to meet the need. Returns on the questionnaires sent to all medical officers are now being received in numbers which clearly reflect the widespread interest in continuation training. Analysis of an early random sample has already been published.¹ Such data are indispensable for effective planning.

Probably 10,000 medical officers will want house officer training of six months or more. Since demobilization will probably extend over some time, the number of additional places required will probably approximate 5,000 during the first year. Apparently most expansion will be required in otolaryngology, surgery, obstetrics and gynecology and ophthalmology, which may need to double their facilities. Expansions of 50 to 70 per cent seem to be indicated in urology, internal medicine, orthopedic surgery and pediatrics.

Somewhat fewer officers are likely to seek shorter courses; about 9,000 officers will seek full time training of one to six months' duration. In 1943-1944 there were nearly 27,000 physicians enrolled in such courses. However, over 90 per cent of these were in short courses of about a month. Apparently more than 90 per cent of those desiring review or refresher courses will seek training in somewhat longer courses of two to six months' duration. Many more courses of that duration will be required.

In the light of the figures given, all institutions which can contribute to meeting the need are obligated to review their resources and prepare estimates of the additional facilities they can provide, to facilitate the achievement of the program outlined (page 257).

The communication from Col. Perrin H. Long, published on page 239 of this issue, further underscores

the deep concern of medical officers with regard to their further training after the war and indicates that the work being carried out by the Committee on Postwar Medical Service meets a real demand. The suggestions of Colonel Long are similar to the program already being developed. With continuing cooperation of the Committee on Postwar Medical Service, the Council on Medical Education and Hospitals, the Surgeons General of the armed forces, medical schools, American boards in the medical specialties and others primarily concerned, there is every reason to expect that the needs will be met. Information now being collected from all educational institutions will be made available in the near future. In the meantime, medical officers can be assured that every effort is being made, and with success, "to cut through to the goal, because then, with the facts before them . . . [medical officers] . . . will be able to plan their existence in the postwar world."

CHANGING FOOD HABITS FOR BETTER NUTRITION

Somebody is always trying to change the eating habits of the American people. Sometimes the stimulus comes from a food faddist who has made up his or her mind that health lies in abstinence from meat or acid fruits or eggs or some other food that has been for years eaten by great numbers of people. Sometimes the urge comes from an agency like the American Meat Institute, the National Confectioners' Association or the manufacturers of cereals or of dairy products or the bakers of bread, telling us that we ought to eat more of their particular products. Associated with these campaigns are the promulgations of groups of scientists or nutritional authorities who want everybody to be quite familiar with the vitamin, mineral, protein, carbohydrate and fat content of everything they eat and to eat strictly according to formula.

Recently a reaction has been voiced in Great Britain against present trends in eating, led largely by Lord Thomas Horder, who is president of the Food Education Society. Lord Horder² said that the overweighting of food education by the appeal to science has induced in many people a spirit of antipathy. They feel that eating and drinking were never intended to be subject to chemical equations. Lord Horder has emphasized the factor of safety in the human body in relation to nutrition. He said, as quoted by the *Lancet*:²

Health is not a tight-rope and our bodies are neither anxious nor solicitous; they are not puritanical; they will dine with publicans and sinners and often, though not always, come away none the worse, but even better. Our bodies are wonderfully adaptable, they will tolerate a large range of strains and stresses. This is not to say that we can continue to abuse our bodies over a long period. But this "balancing" of our diet is sometimes taken too far. The principle is sound and it

1. Lueth, H. C.: Future Educational Objectives of Medical Officers, *J. A. M. A.* 125: 1099 (Aug. 19) 1944.

2. Joy Through Food, editorial, *Lancet* 2: 47 (July 8) 1944.
2. Cautious Food Reform, extract from Lord Horder's presidential address to the Food Education Society, *Lancet* 2: 53 (July 8) 1944.

needed stating, even stressing. Balance the diet by all means; to balance the day's food is not a bad idea; but to balance the individual meal is not necessary at all. . . .

This statement by Lord Horder should give pause particularly to the pronouncements that now assail us constantly over the radio, telling us that this or the other product takes care of all of our deficiencies of vitamins or of minerals or of both. People are likely to get from these announcements the notion that every one is deficient in something or other and that the only hope of health is a superabundance of all the known vitamins and minerals. For them Lord Horder has a special caution:

. . . We should teach a little less than we think we know, rather than strain the few facts of which we seem certain to explain conditions which are complex and probably result from more factors than the few that have been revealed to us.

Supplementing the statement by Lord Horder is one by F. Le Gros Clark,³ who at some length analyzed food habits and how to change them. The eating habits of people are for the most part traditional. Children learn to enjoy certain foods in their homes and carry their prejudices over to adult life. Many of the food habits are a reflection of factors that have nothing whatever to do with the science of nutrition:

Most of those who lecture or write on nutrition are members of the professional classes (research workers, doctors and teachers), whereas most of those who receive the message are the families of miners, dockers, railway men, farm workers and the like. For food habits the latter have acquired in the process of generations there is always a set of comprehensible causes, among which are not only mistaken or outworn ideas about correct diets but also such factors as storage space, cooking facilities, income levels and mealtimes.

Our eating habits are affected by the ability of housewives in general and of cooks to cook. Many a mother has pretty definite ideas about what is good for the family in the way of food, but the preferences of the father and the children are more likely to dictate the dietary than the mother's knowledge of scientific nutrition. If the father and the children refuse to eat turnips or squash or beet tops, the mother gains little by serving these items.

Since established habits of eating are hard to change, more emphasis should be placed on desirable traits in the early impressionable years. The stress on proper feeding of infants and children over the past several years should soon be paying dividends in better eating habits in the younger generation. The gains made should be maintained. Without change in established eating habits, improvement will come from the continuation and expansion of the food enrichment program. Such generally eaten foods as bread, flour, cereals and milk become effective carriers of nutrients which are known to be commonly deficient in diets of the general population. Without change in character of the food, its nutritional value to the consumer is enhanced.

The impositions and restrictions of wartime are without permanence. When restrictions are released, people will go back again to eating what they like. Even the law cannot make people enjoy eating something they do not like. But some benefits on our national nutrition will undoubtedly result from the war aside from the increased scale of food production. There will be new types of food available as a result of research and innovations in transportation. Old familiar foods will be made more attractive to the eye and the palate. The sum total of our wartime food experience can hardly be other than good. Nutritionists and others concerned with the correction of our nutritional delinquencies may extend the gains thus far made. No doubt a planned state would provide community kitchens and dining rooms in which the workers and their families would eat exactly what the nutritionists put out for them, but as long as our civilization continues to be based on the family, food habits are going to control eating.

THE PREVENTION AND TREATMENT OF FETAL ERYTHROBLASTOSIS

Fetal erythroblastosis in by far most cases appears to be the result of Rh incompatibility on part of the father and the mother. Does the demonstration of such incompatibility bring with it practical means for the prevention and cure of erythroblastosis?

At present the main if not the only means of successful prevention would be the avoidance of impregnation of an Rh negative woman by an Rh positive man. The immediate cause of Rh erythroblastosis is the destruction of red corpuscles of the fetus by specific antibodies from the blood of the mother; the question has been raised whether it is possible to remove the antibodies in the mother's blood by injecting the antigen, that is, blood containing the Rh factor. Broman,¹ who has made extensive studies on the Rh factor, introduced blood from the Rh positive father into the isoimmunized Rh negative mother, with an apparently wholly negative result. Further and comprehensive experiments along this line seem indicated. Possibly effective methods of removing antibodies from the mother's blood may be found if the Rh substance becomes available in adequate quantities. In experiments it has been shown that removal of different antibodies from the blood of immunized rabbits readily results from the intravenous injection of the corresponding antigen.

Henceforth special care must be taken in blood transfusion of prospective mothers. Rh negative women in the childbearing age should not be transfused with Rh positive blood because, if done, Rh antibodies may be produced which can cause erythroblastosis in a subsequent Rh positive fetus. The sensitization of an

3. Clark, F. Le Gros: Food Habits and How to Change Them, *Lancet* 2: 53 (July 8) 1944.

1. Broman, Birger: The Blood Factor Rh in Man: A Clinico-serological Investigation with Special Regard to Morbus Hemolyticus Neonatorum (Erythroblastosis Fetalis), *Acta pædiat.* 31, Supp. II, 1944.

Rh negative woman to the Rh factor may be harmful to the future offspring.

In the case of Rh incompatible couples with previous erythroblastic episodes, the mother may be tested at intervals for Rh antibodies if pregnancy occurs again with a view to producing premature viable birth, should the results be increasingly positive. As yet the suggestion has not been approved by obstetricians. The experience so far indicates "that nothing is to be gained by premature delivery."² Whenever there is reason to fear erythroblastosis, arrangements should be made so that if necessary transfusion of the child with suitable Rh negative blood can be done as soon after birth as possible. There are as yet no methods available for intrauterine control of erythroblastosis. Treatment can be given after birth only. Since some 50 per cent of children with erythroblastosis die before they are 7 days old¹ the earlier proper treatment is given the better. The treatment of choice³ is the introduction of Rh negative blood—a substitution treatment. Rh negative blood of the same group as that of the infant is used because there may be anti-Rh bodies in the blood and tissues of the child. Fortunately suspensions of the mother's red cells can be used after thorough washing in salt solution to remove all traces of the plasma. It has been recommended that infants with erythroblastosis be not nursed by their mothers because the milk may contain anti-Rh bodies.⁴ It was noted long ago that infants with erythroblastosis did not thrive on the mother's milk. The results of prompt transfusion in erythroblastosis are favorable.⁵ In Javert's series the case death rate was reduced from 73 to 14 per cent.

EXIT TALCUM FROM THE SURGICAL SCENE

From the earliest days of the emergence of surgery in the fertile valley of the river Nile down to Ignatz Semmelweis's epochal discovery, surgeons with few exceptions shared with the rest of humanity the title of the "great unwashed." Then, in 1861, hand washing emerged from the realm of Mosaic ritual into the sphere of inviolable surgical technic. About forty years later came the discovery, after Pasteur's and Lister's investigations, that mere hand washing was not adequate protection either for patient or for surgeon; therefore sterile cotton or lisle gloves were added to the surgical armamentarium. Only a few years later Halsted supplanted fabric with rubber gloves sterilized by boiling

and put on under sterile water or a suitable antiseptic solution. This technic in turn, and in short order, was replaced by steam autoclaving of the rubber gloves and donning them when dry, with the aid of the generous use of talcum powder. This powder was dusted inside the gloves before and also after sterilization, and on the hands of the surgeon before slipping them into the gloves.

That talcum and similar powders are not innocuous has been known for well over half a century. In 1881 Hippolyte Martin¹ described the potentially grave hazards incident to the use of these powders. Only well within the past ten years, however, have surgeons and pathologists recognized the dangerous properties of talcum powder. More than a score of studies have been published detailing the serious consequences that follow the entrance of talcum powder into animal tissues by way of operative wounds, the peritoneal cavity, the brain, the rectum, the vagina or the cervix and through numerous other routes.

The resultant lesions follow a definite structural pattern, which initially is that of the usual foreign body reaction represented by tubercle-like formation, with talc crystals demonstrable in most of the tubercles. This demonstration is greatly facilitated by the use of polarized light. Later a fibrosis occurs. Naturally when these processes occur in the peritoneal cavity they lead to peritoneal adhesions frequently causing intestinal obstruction. These lesions are permanent because the body does not have adequate reparative power against talcum, which is essentially a silicate and which therefore induces a silicosis.

The evils of talcum manifest themselves most tragically in the field of abdominal surgery in the form of postoperative intestinal obstruction. German² studied a series of surgical patients by removing biopsy specimens from the omentum in 50 cases in which laparotomy had been done. Using polarized light technic he demonstrated the presence of talc crystals in 80 per cent of the specimens. These results of German's study furnish startling and disturbing evidence of the frequency with which talcum escapes into the peritoneal cavity during operative procedures. It does not always follow, of course, that the presence of intraperitoneal talcum invariably causes symptoms of grave abdominal disease; but it requires no stretch of imagination to grasp the possible hazards attendant on the presence of a siliceous powder in the peritoneal cavity.

Despite these hazards, however, and despite an appreciable wealth of scientific literature on the subject, investigators³ at the Barnard Free Skin and Cancer Hospital of St. Louis were the first to

substitute an innocuous powder for the troublesome talcum. These workers present evidence favoring the use of potassium bitartrate (cream of tartar) as a desirable and safe substitute for talcum. This salt is readily disposed of by the body fluids and tissues within a few hours and has the added advantage of being bacteriostatic in its action. It does not deteriorate rubber, but it is a bit more costly than talcum powder. In a later contribution the Barnard Hospital workers⁴ announced the discovery by which corn starch can be robbed of its gelling property and thus rendered even more suitable as a dusting powder than is potassium bitartrate, because it is smoother in texture and is more readily disposed of by the diastase mechanism of the body. This new, nongelling starch cannot be manufactured until after the cessation of war, owing to problems of priorities. In the meantime the somewhat more costly potassium bitartrate will serve. In any event the surgical scene seems to be set for the exit of talcum.

HEAT PRODUCTION ON MIXED DIETS

During the last decade Forbes and his associates¹ of the Institute of Animal Nutrition, Pennsylvania State College, have collected experimental evidence that with animals on equicaloric mixed diets progressive decrease in total heat production is associated with increases in protein percentage. This is contrary to general clinical belief, which assigns a dominant thermogenic role to protein. Forbes and Swift² have emphasized the possible bearing of these results on current problems of military dietetics and animal husbandry.

Total heat production was measured in selected groups of white rats during seven hour experimental periods on two consecutive days, the animals sleeping during most of the period. The first determinations were made with the animals on a minimum basal diet. The experiment was repeated seven days later with the same rats on the same diet plus measured amounts of beef protein, dextrose or lard, tested alone or in combination. The increased heat production on the supplemented diets was taken as a measure of the energy expense of utilization of the supplement. Accepting this interpretation, the net energy value of the supplement was calculated by subtracting this caloric expense of utilization from the gross caloric value of the supplement.

When fed alone it was found that 32 per cent of the total caloric value of beef protein was expended as necessary expense of utilization. With dextrose 20 per cent of the total caloric value was thus expended and with lard 16 per cent. The calculated net energy values of these three foods were protein 68 per cent of the gross caloric value, carbohydrate 80 and fat 84.

When these three foods were mixed, however, the heat production (energy of utilization) was much less than that computed from the individual food components. Thus, with a mixture of approximately equal parts of beef protein and lard but 11 calories of energy was necessary for utilization, as compared with 24 calories calculated for the individual components, a reduction of 54 per cent in the energy expense of utilization. Dextrose plus lard led to an "economy of utilization" of 35 per cent, dextrose plus protein 12.5 per cent and dextrose plus protein plus lard 22 per cent. It is evident from these data that in mixed diets carbohydrate is the major thermogenic factor, while lard is the major factor conferring economy of utilization.

The results of this study suggest that there is no special reason for decreasing the protein content in tropical military diets. Any desired decrease in heat production should be accomplished first by diminishing the carbohydrate, second the protein and last of all the fat in the routine mixed diet. The study also emphasizes present economic losses in animal husbandry. Manufacturing processes which skim off the fat content of by-product feed not only lower the net energy value of the feed through diminishing its gross caloric value but also decrease its net nutritional value by increasing the caloric expense of its utilization.

No adequate theory has thus far been suggested to account for the observed antithermogenic effects of fat in a mixed diet.

CONGENITAL CATARACT AND OTHER ANOMALIES FOLLOWING GERMAN MEASLES IN THE MOTHER

Gregg reported in 1941 at the annual meeting of the Ophthalmological Society of Australia a series of 78 cases of congenital cataract occurring in babies between December 1939 and January 1941. With few exceptions their mothers had suffered during the early stages of pregnancy from an exanthematous disease diagnosed as rubella. Many of the babies were of small size, ill nourished and often difficult to feed. In 44 of them a congenital lesion of the heart also was detected, in 10 the heart was apparently normal and in the remainder the cardiac condition was not recorded. The cataracts were of dense nuclear type; in 62 cases they were bilateral and in the remainder unilateral. In 11 of the 16 monocular cases the affected eye was microphthalmic. There was no similarity in the appearance of the cataracts to any of the morphologic types of congenital and developmental opacity reported previously.

Swan and his collaborators¹ investigated, under the grant from the National Health and Medical Research Council, children born in South Australia of mothers

1. Swan, Charles; Tostevin, A. L.; Moore, Brian; Mayo, Helen, and Black, G. H. Barham: Congenital Defects in Infants Following Infectious Diseases During Pregnancy, with Special Reference to the Relationship Between German Measles and Cataract, Deaf-Mutism, Heart Disease and Microcephaly, and to the Period of Pregnancy in Which the Occurrence of Rubella is Followed by Congenital Abnormalities, M. J. Australia 2: 201 (Sept. 11) 1943.

who had suffered from exanthematous disease during pregnancy. Of 61 infants examined, 36 were found to have congenital defects. The mothers of 49 infants had suffered during pregnancy from rubella, 4 had no knowledge of any exanthem during this time, 9 contracted measles during pregnancy and 2 suffered from mumps. In the cases of rubella during pregnancy 31 of the infants born subsequently exhibited congenital defects. The abnormalities included cataract, deaf-mutism, heart disease, microcephaly and mental retardation. With 2 exceptions all of the 31 mothers with congenitally defective children had contracted rubella within the first three months of pregnancy. No congenitally defective babies were born subsequent to the occurrence of measles in pregnancy. One case is recorded of congenital corneal opacity following mumps.

Gregg noted that the epidemic of German measles in 1940 which gave rise to most of these cases was of greater severity and was more often accompanied by complications than previous epidemics of his experience. In some of the cases of the series investigated by Swan and his associates the general constitutional symptoms and the occurrence of complications were more pronounced than usual. The Swan committee gained the impression that the disease was sometimes more intense in mothers who later gave birth to congenitally defective infants than in those whose children were born healthy. The severity of the epidemic of German measles of 1940 was probably caused by the war conditions, large numbers of susceptible recruits being herded together in military camps. The disease spread rapidly, and the causative agent may have reached a higher stage of virulence. Several investigators have shown that avian and mammalian embryos exhibit a much higher susceptibility to infectious agents than adult tissues. Possibly the human embryo possesses the same susceptibility to infection, and the etiologic factor of German measles, after penetrating the chorionic barrier, is capable of producing severe lesions in the embryo, whereas the same infection in the adult tissues of the mother leads to only minor effects. Data gathered by Swan and his collaborators suggest that the chances of giving birth to a congenitally defective child when a woman contracts rubella within the first two months of pregnancy are almost 100 per cent, and if she contracts rubella in the third month they are about 50 per cent.

Now Reese² reports from New York City congenital heart lesions in 3 infants. The mothers of these 3 infants contracted German measles within the first month of pregnancy, which was during a rather severe epidemic of German measles in the East about one and a half years ago. This author raises the question whether the exanthem in the mother was German measles and, if it was German measles, why congenital anomalies in the

children so infected have not been observed before. A probable answer is that the congenital anomalies in his cases are the result of a more virulent or probably altered type of virus, which may have gained access to this country through an increased traffic with Australia.

Current Comment

HOSPITAL FACILITIES FOR TREATMENT OF ALCOHOLISM

An exhaustive report¹ on the institutional facilities available in this country for the treatment of alcoholism has recently been prepared by a committee of the American Hospital Association; its conclusions can be accepted as the basis for further study and active implementation. Hospital facilities for the care and treatment of alcoholic addicts in the United States are scanty and inadequate, and those which exist are not always utilized to the best advantage. The placement of patients in institutions has depended to a greater extent on the admission policies of hospitals, economic status of the patient, and how much of a nuisance he has been to his family or to the public than it has on the type of medical management best suited to his case of inebriety. Furthermore, there has been a lack of understanding of the necessity of research directed toward the evaluation of various technics of treatment, of the need to explore new methods of therapy and the necessity of greater education of physicians and those in allied professions in the sound handling of the problem drinker. The main point of attack, it is stated, should be through the general hospital. The completeness of the facilities of the general hospital and its accessibility make it the most logical place to which an alcoholic addict or his family would turn. The alcoholic addict, like other patients suffering from acute manifestations of an underlying chronic disorder, should not be denied the advantage of a thorough study of the cause, or causes, of his condition, or advice as to the means by which it can be best treated. Although some general hospitals may object to including facilities for patients with alcoholism, the report emphasizes the overwhelming arguments for the extension of their use in this manner. The report recommends that the trustees of the American Hospital Association appoint a committee to translate the suggested program into action; its scope should include the dissemination of facts, the stimulation of discussions of the problem, the setting up of selected hospitals as experimental units for testing the possibility of incorporating the treatment of alcoholic addicts into a well integrated plan and the promotion of clinics in outpatient departments and representative hospitals. In view of the profound effect which alcoholism has on a large and often otherwise useful segment of the population, the recommendations of the committee should receive active support by individuals, philanthropic foundations, general hospitals and all others who can exert any influence on this probably growing medical and social problem.

MEDICINE AND THE WAR

GRADUATE MEDICAL TRAINING IN THE POSTWAR PERIOD

To the Editor—While looking over the "Program of the One Hundred and Sixty-Third Anniversary of the Massachusetts Medical Society," I noted that Dr. Allen O. Whipple was to present a paper on the subject of "How Shall We Provide Postgraduate Training in Surgery for Men at Present Serving in the Armed Forces?" While I have not had the privilege as yet of reading Dr. Whipple's address, I would like to discuss, from the point of view of a medical officer in an overseas theater of operations, the problem of postgraduate medical education for doctors who at some future period will be demobilized from the armed forces.

During the past year I have had repeated opportunities to discuss this problem with those who are most concerned with it, namely the doctors who staff the medical services of squadrons, battalions, regiments, divisions, corps, armies and those whose duties are of a nonprofessional nature in administrative sections and depots. In addition, this question has been reviewed with doctors in field, evacuation, station and general hospitals. It is believed from these discussions that an attempt can be made to gauge the cross section of opinion of these doctors on the problems of postwar professional rehabilitation, their reactions toward what has been accomplished so far in this direction and to formulate the tentative desires of at least a section of the doctors in the armed forces in respect to what they would like in the way of postwar postgraduate medical education.

It seems quite clear that most of the doctors whose tour of duty has been a professional one in station or general hospitals for the greater part or all of their service in the armed forces will require much less professional rehabilitation than those who have been in field service or administrative positions. Hence for doctors who have been in hospitals, short intensive postgraduate courses dealing with cardiology, degenerative diseases, metabolic and endocrinologic disturbances would seem desirable. These men have not lost that type of analytic reasoning which is based on the correct evaluation of all factors involved and which is necessary for arriving at the diagnosis and forms the basis for the treatment and prognosis of disease.

The problems of doctors who have been in field or administrative services are entirely different. These are the men whose closest contact to professional practices for periods which in some instances amount to four years has been to hold sick call if they are field service doctors or none at all, as is the case with many of the doctors who hold administrative positions. Experience has shown when these men are rotated to positions as ward doctors in station or general hospitals, that from three to six months is required to reeducate them in analytic reasoning and to restore their confidence in their professional ability. This observation gives a definite clue to the length of the periods of instruction which will be required and programs for rehabilitation should be formulated so that these doctors will receive carefully supervised ward and outpatient work with patients, together with formal ward rounds, clinics and lectures on special topics, x-ray and clinical pathologic conferences and journal clubs during their period of postgraduate instruction. These men have had little opportunity to acquaint themselves with the advances in medicine which have been made since 1940. Because of their long separation from professional practices, these field and administrative medicine officers should be given a first priority on all courses in postgraduate instruction, and this priority should be continued until demobilization is complete.

Then there is a third group of doctors with whom we should concern ourselves and whose problems are not so well understood by those of us who have long been without the continental limits of the United States. These are the young men who have undergone a forced acceleration of their medical education and hospital experience in medical schools and hospitals whose staffs have been woefully depleted during the past three years. One can judge these young doctors only by their performance,

and to date our experience with them has not been broad enough to warrant any conclusions being drawn. However, it seems logical to assume that their foundation in medicine is less adequate than the foundation of those who graduated prior to June 1942. For these young men definite plans for further instruction must be made, otherwise they will be on the market at a dime a dozen in the competition for internships and residencies which will arise in the postwar period, and unless suitable preparations for their reception back into hospital training are made a chaotic situation characterized by disappointment, bitterness and resentment on the part of these young men to their chosen profession will arise.

That the future of our profession in a large measure is dependent on the maintenance of high standards of professional practice is well recognized by the doctors in the armed forces and is the reason why they are hoping and one might even say praying that means will be afforded for the professional rehabilitation which will be necessary if our standards are to be maintained in the postwar period. It is at this point that emphasis must be laid on the point that these doctors are beginning to develop an attitude of hopelessness toward their chances of postwar postgraduate education because of the lack of a specific program for rehabilitation which would permit them to begin to lay plans for the future. One looks in vain in the Report of the Committee on Postwar Medical Service (*THE JOURNAL*, June 24, p. 567) for a real ray of hope. All that one finds, and I quote, "Authorization has now been obtained to send a somewhat revised questionnaire to all medical officers in the Army, Navy and Public Health Service." I think it is safe to say that these questionnaires will receive a very favorable response. It will make the medical officers feel that they are not forgotten men. "The committee submits this report of a record of a year's humble but earnest endeavor." A questionnaire to make medical officers realize they are not forgotten men! Furthermore, in the President's address (*THE JOURNAL*, June 17, p. 461) the statement is made that "the Association is doing everything in its power to safeguard the quality and standard of medical practice during your absence and will do everything in its power to aid you when you return. The Council on Medical Education and Hospitals has made an extensive study of existing facilities for graduate medical education and is giving thought to the establishment of further facilities so that medical officers who have had an abbreviated internship or whose residency was interrupted may, on return, complete their education." These are hopeful phrases to be sure, but if the study has been made why not immediately publish its results so that doctors in the armed forces may begin to plan for the future and instead of giving "thought to the establishment of further facilities" for medical officers who have had abbreviated training, why not say that they will be made available and by utilizing the prestige and power of the Association create promptly a reality from the thought?

It is not that doctors in the armed forces are critical or resentful of the effort being made by the Association in their behalf, they are merely skeptical of its realization. While it would be foolish to presume to answer for all the doctors in the armed forces a cross section of the opinions of a rather large group of doctors in the armed forces would lead one to believe that the following specific information should be made available in the very near future to these men:

What facilities will exist for further hospital or postgraduate training in the demobilization period?

(a) What medical schools and hospitals will provide such training?

(b) What will be the length of the periods of training and postgraduate courses?

(c) What will be the content of the training and postgraduate courses?

(d) Where will one be able in the near future to obtain information in respect to postwar training?

(e) When and where will one make application for this training?

(f) What will be the cost of this training and will it be subsidized by private or governmental agencies?

The complexity of these problems is well understood by the doctors in the armed forces, but they feel that every effort should be made to cut directly through to the goal, because then, with the facts before them, they will be able to plan their existence in the postwar period.

PERRIN H. LONG, Colonel, M. C., A. U. S.

ARMY

HOSPITAL SHIP PATIENTS WRITE IN PRAISE OF EXCELLENT CARE

The War Department announced that letters written by patients who have returned to the United States from the fighting fronts aboard army hospital ships show the sincere gratitude these sick and wounded men feel for their treatment during the ocean voyage. Some of these letters were addressed to the senior medical officer aboard ship or to the master.

The Transportation Corps, responsible for the operation of these floating hospitals, has twenty of them in operation, most of which are busy in the Atlantic and the Mediterranean, bringing back the wounded from France, Italy and Africa. The great majority of their passengers have been disembarked at the Charleston, S. C., Port of Embarkation.

In a letter signed by 4 patients, the men stated "Our quarters have been to us the essence of luxury embracing all those essentials to complete comfort we had been looking forward to renewing our acquaintance with. All the members of the Medical Corps, doctors, nurses and wardmen have unstintingly and cheerfully done their utmost to make us happy, comfortable, and to speed our recovery. Never shall we forget for a moment our great indebtedness to them all."

These "floating hospitals" can anchor off an invasion coast and take care of any need of a wounded man. Completely equipped with the latest medical and surgical devices and staffed with picked medical personnel, the wards aboard these vessels compare favorably with any. Drill in abandoning ship has been given until each member of the staff knows how to evacuate patients quickly and efficiently. In accordance with international agreements, hospital ships are painted white with a wide green band around the middle and marked with huge red crosses.

APPOINTED ASSISTANT SURGEON FOR THE NATIONWIDE ARMY AIR FORCES TRAINING COMMAND

Col. W. H. Powell Jr., formerly of Fayetteville, N. C., has been appointed assistant surgeon for the nationwide Army Air Forces Training Command. He previously served as chief of the Professional Service section of the Training Command Surgeon's office. Dr. Powell will assist in the direction of medical, surgical and related functions at AAF flying and technical schools in every corner of the nation. He entered the army as a 1st lieutenant at Fort Bragg, North Carolina, in December 1929, where he was accepted for appointment to the regular army. He graduated from the Medical College of Virginia, Richmond, in 1927. He is also a graduate of the Army Medical School, Washington, D. C., of the Medical Field Service School, Carlisle Barracks, Pa., of the radiology course at the Army and Navy General Hospital, Hot Springs, Ark., and of the School of Aviation Medicine, Randolph Field, Texas.

GEN. DWIGHT D. EISENHOWER PAYS TRIBUTE TO ARMY NURSES

A tribute to the work Army nurses are doing in the European theater was recently expressed by Gen. Dwight D. Eisenhower in a letter to Mr. Edwin B. Wilson, editor of the *Brooklyn Eagle*. General Eisenhower had been informed by Mr. Wilson of the campaign being undertaken by the *Brooklyn Eagle* and by the Brooklyn chapter of the Red Cross to recruit nurses for the armed forces. Expressing his appreciation of the nurses' work, General Eisenhower wrote "Nothing stops them in their determination to see that our troops receive

the best attention humanly possible. . . . We need nurses, more nurses. The work that you and your group—and other similar groups throughout the United States—are doing must be successful."

HOSPITAL STAFFED BY GERMAN DOCTORS OPENED IN OKLAHOMA

The Army Medical Department has established a separate prisoner of war hospital staffed with doctors and medical corps men of the prisoner's nationality. The first hospital, Glennan General Hospital, with a bed capacity of 1,700, has been established at Okmulgee, Okla., for German war prisoners. American Army doctors are the chiefs of the medical services. Eight German physicians have been assigned to medical work. It is anticipated that the number will be increased to 30 or 40.

The Medical Department's new policy is in accord with the Geneva Convention Treaty, which stipulated that "it shall be lawful for belligerents reciprocally to authorize, by means of private arrangements, the retention in camps of physicians and attendants to care for prisoners of their own country."

PHYSICAL THERAPY CLINIC IN THE JUNGLE

A physical therapy clinic was created recently out of makeshift materials by members of a hospital unit on the Ledo Road, the highway which Allied troops are building from Assam, India, through Burma to China against the vigorous opposition of the Japanese. Lieut. Col. Willis M. Weeden of Woodbury, Conn., chief of surgery in the unit, assigned Capt. Hyman D. Stein of Elkins Park, Pa., and 2d Lieut. Pauline Moudy, Army Nurse Corps, of Alhambra, Calif., to the task. They made a dry heat apparatus out of a crate and electric bulbs. Stirrups with ropes and weights made weight lifting devices, a Chinese officer provided a bicycle for leg exercises, and old gasoline tanks were turned into whirlpool leg and arm baths. A water heater was created from a gasoline drum, and the hard rubber core of an old soft ball was used for hand and finger exercises.

ELECTRICALLY HEATED FLYING SUITS DELIVERED TO ARMY AIR FORCES

The General Electric Company recently delivered to the Army Air Forces the 200,000th electrically heated flying suit. The suit consists of jacket, trousers, gloves, boots and other electrically heated accessories. Each product has been subjected to a great variety of tests. Proof of the suit's ability to withstand the low temperatures encountered by airmen at high altitude has come in actual combat. Without the protection these suits afford, airmen fall easy prey to their invisible enemy frostbite. Major H. G. Thole of the AAF matériel command accepted the suit on behalf of the Air Forces from D. C. Spooner, manager of the pioneer products section of the General Electric Company, which developed the outfit.

SCOPE OF WORK AT MOORE GENERAL HOSPITAL

The Office of the Surgeon General of the Army, clarifying a recent announcement of the designation of the Moore General Hospital, Swannanoa, North Carolina, as a medical center for the study and treatment of tropical diseases, points out that the

commanding officer of the hospital is Col. Frank W. Wilson and that the chief of the medical service is Lieut. Col. Joseph M. Hayman, under whose professional direction the tropical disease center will operate. The center will not confine its attention to malaria.

CHARLES A. STAFFORD (EX SIBONEY) DESIGNATED AS U. S. ARMY HOSPITAL SHIP

The War Department announced on August 1 that on May 20 the *Charles A. Stafford* (ex *Siboney*) was designated as a United States Army hospital ship, in accordance with international practice, as set forth in the provisions of the Hague Convention X of 1907. In the future the United States Army hospital ship *Charles A. Stafford* will be operated in accordance with the provisions of applicable treaties. Notification of this designation was delivered, through channels, to the German, Japanese and Thai governments on June 3, to the Rumanian and Bulgarian governments on June 6 and to the Hungarian government on June 9. The ship's master of this and all other United States military hospital ships will at all times maintain sufficient copies of this general order for presentation to any authorized agent of an enemy belligerent who may require it for inspection.

MAJOR MANTZ APPOINTED CHIEF OF MALARIA CONTROL SECTION

Major Francis A. Mantz of Bala-Cynwyd, Pa., has been appointed chief of the Malaria Control Section in the Preventive Medicine Service, Office of the Surgeon General. Dr. Mantz has been stationed overseas as malariologist for the past three years, lastly in the China-Burma-India theater, to which he was assigned early in January 1943. Dr. Mantz graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1938 and entered the service July 1, 1941.

LIEUT. ARTHUR L. BENISON A PRISONER OF WAR

Word has recently been received by the parents of Lieut. Arthur L. Benison, formerly of Flint, Mich., that he has been held prisoner by the Japanese at Philippine Military Prison Camp No. 1 for more than two years. He was believed to be taken prisoner at Bataan. Dr. Benison graduated from the University of Michigan Medical School, Ann Arbor, in 1937 and entered the service May 15, 1941.

ARMY AWARDS AND COMMENDATIONS

Captain Harry J. Stone

The Distinguished Service Cross was recently awarded to Capt. Harry J. Stone for "extraordinary heroism in action near Anzio, Italy." The citation accompanying the award read:

"On Jan. 27, 1944 Captain Stone advanced with a company attacking in daylight across an exposed field. During the advance the enemy laid down heavy concentrations of artillery and machine gun fire on the unit. Carrying full equipment, Captain Stone kept pace with the foremost elements and, following the assault, maintained an aid station under direct enemy observation.

"Captain Stone's prompt treatment under fire was a vital necessity, since evacuation was impossible because of direct enemy observation and nearness of enemy positions.

"Four days later his battalion occupied a defensive position and was subjected to heavy and sustained enemy attack. Because of enemy observation and fire, the position could be approached only at night. Despite heavy enemy fire, Captain Stone made nightly trips to the position to evacuate the wounded. On the night of March 15-16, 1944 Captain Stone participated in an advance on two enemy strong points. Following the assault platoon under intense artillery and machine gun fire, he treated 2 casualties directly in the rear of the objectives. Leav-

ing his place of cover, he then proceeded under continued heavy fire to treat 2 more men in an open field swept by machine gun fire. Despite the intensity of artillery and small arms fire, he carried to safety 1 of the men who was unable to walk. Still under fire, he went to the aid of 5 other casualties. During the following hours of continuous combat, Captain Stone was ever available to render aid where needed. With no regard for his own safety, he promptly treated and evacuated all casualties.

"His calm demeanor and sustained courage and skill under fire were an inspiration to all officers and men, and his performance reflects the finest traditions of the Medical Corps."

Dr. Stone graduated from Wayne University College of Medicine, Detroit, in 1938 and entered the service Aug. 1, 1942.

Major Ernest Lloyd Boylen

The Bronze Star has been awarded to Major Ernest Lloyd Boylen, formerly of Portland, Ore., for meritorious service in direct support of combat operations in Italy last December and January. He commanded, within a few miles of actual combat, a field hospital unit which, according to the citation, "admitted numerous patients too seriously wounded to permit evacuation to the rear. Major Boylen so organized the hospital as to provide the highest type of surgical and medical treatment to these patients. He displayed outstanding executive ability and resolved numerous problems of administrative and supply work incident to this function. His efficiency and devotion to duty contributed greatly to the high rate of recovery of seriously wounded patients during this period." Besides the Bronze Star awarded Dr. Boylen, his unit received a Fifth Army Plaque and clasp "for outstanding performance during January 1944." Dr. Boylen graduated from Harvard Medical School, Boston, in 1926 and entered the service Aug. 8, 1942.

Captain Lucien M. Strawn

The Silver Star Award for gallantry in action has recently been presented to Capt. Lucien M. Strawn, a battalion surgeon serving with the infantry in France. The citation accompanying the award said "Capt. Strawn's battalion was engaged in a bitter fight against a powerful enemy force. Observing many wounded and knowing their immediate need for medical attention, Capt. Strawn went forward into the heavy fire to administer first aid, with complete disregard for his own personal safety. His action saved many lives, and in performing it he displayed outstanding courage and devotion to duty. Capt. Strawn's decision to go forward through terrific enemy fire and help his fellow soldiers is in keeping with the highest soldierly and professional traditions." Dr. Strawn graduated from Temple University School of Medicine, Philadelphia, in 1940 and entered the service Aug. 18, 1942.

Colonel Emory H. Gist

Col. Emory H. Gist, camp surgeon and commanding officer, Regional Army Service Forces Hospital, was awarded the Camp Lee Certificate of Commendation for "exceptionally meritorious service" by Brig. Gen. George A. Horkau, camp commander. The citation states that Colonel Gist "supervised the growth and the extensive expansion of the station hospital, and, to a large extent, its present status as an Army Services Forces Regional Hospital is a tribute to his outstanding administration." The Certificate of Commendation adds that "through his guidance an enviable high standard of health has been maintained on this post; rigid sanitation and the control of diseases and injuries have been factors in this success." Dr. Gist graduated from Barnes Medical College, St. Louis, in 1911 and has been a regular army officer since 1922.

Captain Charles A. Speer

Capt. Charles A. Speer, formerly of Somerville, N. J., has been awarded the Silver Star for gallantry in action in France on D day, June 6. He has also been awarded the Purple Heart. Dr. Speer has been serving overseas with the Army Medical Corps since October 1942. He has received battle stars for three major engagements besides the invasion of Normandy, having seen action previously in Tunisia, Bizerte and Sicily. Dr. Speer graduated from New York University College of Medicine, New York, in 1940 and entered the service June 2, 1942.

MISCELLANEOUS

DOCTOR'S MISSING BOOK FOUND WITH DEAD JAP

When Dr. Edwin Lee of Downey, Calif., was a student at Loma Linda Medical College an instructor told the students to buy Kellogg's Surgical Approaches to Anatomy. Dr. Lee bought his volume and put his name on the fly leaf. One day it vanished from his book shelf. He sought it in vain and finally bought another. The other day he received the book from a former classmate, Major L. Lawrence Whitaker, medical officer with the American forces that took Attu. The major and another Loma Linda classmate had discovered it in a Japanese hospital on the island, following the occupation by the Americans. A letter from Major Whitaker told Dr. Lee of the weird incident of finding the book. After the Americans had completed the bitter job of wiping the tenacious Japs out of Attu, Major Whitaker and a group of officers examined the garrisons where the Jap command had its headquarters. When they entered the underground hospital they found that 18 of the Jap wounded had been killed by morphine. They lay on their backs, their hands folded across their chests, stiff in cold death. The doctor who had killed his patients lay sprawled on the floor—he had put a bullet through his head. Major Whitaker and his classmate recognized the doctor as their former classmate Paul Tatsuguchi, who had been in college with them for four years. He had received his medical degree with them and had taken the California state medical examination with them when they did.

The two officers found his personal effects and, in going through them, discovered a diary which he kept in English during the last sixteen days, when the Japs realized that resistance would prove useless. He related what was happening as the battle of Attu began depleting the Jap garrison and wounded soldiers were being brought to the hospital. He methodically set down the number of patients he was treating and what he was doing for each one. He told how he had contracted diarrhea and how ill he was. On the last day, when the Japs knew that the end had come, he described how he had killed each of his patients. He wrote a farewell note to his wife and two children who lived in Japan. In final rite he wrote a rededication of himself to his emperor, setting down a renewal of his oath and then, according to the grim evidence, took his life.

In addition to the diary, one of the Loma Linda classmates picked up a volume that had a familiar appearance; it was "Surgical Approaches to Anatomy," a book that recalled many memories. The two officers examined it, and there on the fly leaf they found the name of Ed Lee. It had been crossed out and beneath it was written that of Paul Tatsuguchi.

U. S. HOSPITALS ASSURED ENOUGH SUPPLIES AND EQUIPMENT FOR TREATMENT OF POLIOMYELITIS

The War Production Board's Office of Civilian Requirements recently announced that hospitals of the United States have been assured enough supplies and equipment to treat every one of the approximately 9,500 cases of poliomyelitis reported in the current epidemic and two and one-half times that number if they should develop. Warned in June by the rapid development of the epidemic in North Carolina and Kentucky and the occurrence of 480 cases nationally, the OCR Chemicals, Drugs and Health Supplies Division officials contacted the National Institute of Health and the National Foundation for Infantile Paralysis to determine what equipment would be needed and what was available. It was revealed that 150,000 yards of wool, 500,000 yards of muslin binder, 150,000 yards of oil silk, 100,000 blankets and 25,000 dozen safety pins would be needed, together with hot pack units. Three days later the first hot pack unit thus made available was shipped by the maker to a hospital in Washington, D. C. Three more were sent to North Carolina, 15 went to Buffalo, and other orders were being filled.

Throughout the summer OCR acted as a clearing house, putting hospitals in touch with sources of equipment and sup-

plies and manufacturers in touch with materials. Contacts were made for inquiring parties and emergency ratings issued when necessary. OCR officials believed there would be little difficulty in meeting future emergency demands. Cooler weather is expected to help stop the spread of the disease.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, September 16, page 177)

ILLINOIS

Illinois Central Hospital, Chicago. Capacity, 290; admissions, 5,378. Dr. W. W. Leake, Chief Surgeon (interns, resident).

NEW YORK

Ellis Hospital, Schenectady. Capacity, 470; admissions, 14,385. Miss Mary G. McPherson, R.N., Administrator (intern, October 1).

PENNSYLVANIA

Babies Hospital, Philadelphia. Capacity, 14; admissions, 235. Dr. Laura E. McClure, Medical Director (resident—pediatrics, October 1).

WISCONSIN

State of Wisconsin General Hospital, Madison. Capacity, 772; admissions, 13,393. Dr. H. M. Coon, Superintendent (resident—surgery).

U. S. DOCTORS SAVE TWO HUNDRED JAVANESE

The lives of more than 200 Javanese workers were recently saved after being treated by American doctors when General MacArthur's men invaded Numfoor Island, a Japanese held air base at the entrance of Geelvink Bay, off the northwest coast of Netherlands New Guinea on July 2. Hundreds of Indonesians had been transported there from other Netherlands East Indies Islands to work on defense projects. Some were on the verge of death as a result of starvation, overwork and disease. Medical personnel of American hospital ships were immediately assigned to treat these workers, a number of whom were in such critical condition that they needed blood transfusions. Most of the victims of Japanese cruelty pulled through, but some were beyond help and died en route to Australia.

WOMEN GIVEN BRAVERY AWARDS

The Office of War Information recently announced that awards from the Army and Navy for bravery and efficiency in war have been presented to 105 American women. Army nurses lead with 97 and a Distinguished Flying Cross, the highest award ever given an American woman in uniform. This was presented to Lieut. Kathleen R. Dial of Florence, Ala., in recognition of her work in taking care of 18 patients after a flying ambulance crashed off Port Moresby, New Guinea.

Flying nurses have received 29 air medals, 11 with four oak leaf clusters, for flights in combat areas. Twenty-four Purple Hearts have been received by Army nurses and four by Wacs. The Soldier's Medal for personal bravery has been presented to four Army nurses and two Wacs.

HEALTH NEWS FROM EUROPE

The Netherlands Information Bureau recently stated that diphtheria has increased thirtyfold in occupied Holland, with a weekly average of 1,800 new cases reported for the country. According to information gathered by medical personnel of the Nazi government, deaths resulting from diphtheria totaled 2,382 in 1943, as compared with the 75 reported in 1939 prior to the Nazi occupation. The tuberculosis toll has doubled within this period, the reports also revealed. In 1939 the number of deaths due to this disease was 3,595, while in 1943 it rose to 6,382.

ORGANIZATION SECTION

POSTWAR MEDICAL SERVICE

A meeting of the Committee on Postwar Medical Service was held on September 9 at the Waldorf Astoria Hotel in New York City. The following members and guests were present: Dr. Roger I. Lee, chairman, Dr. Irvin Abell, Dr. Francis G. Blake, Dr. F. F. Borzell, Dr. Frederick A. Collier, Mr. Graham E. Davis, Dr. Morris Fishbein, Dr. Alan Gregg, Dr. Charles M. Griffith, Mr. B. A. Horning, Dr. E. E. Irons, Dr. Victor Johnson, Mr. E. R. Loveland, Lieut. Col. Harold C. Lueth, Dr. W. W. Palmer, Col. George M. Powell, Dr. W. C. Rappleye, Father Alfonse Schwitalla, Miss Mary Switzer, Dr. Olin West and Dr. Ralph C. Williams.

The chairman reported the loss of a valued member of the committee, Dr. William C. Breed of Boston, who died in August, and stated that the vacancy thus caused would be filled by the appointment of Dr. Morris Piersol of Philadelphia.

REPORT ON QUESTIONNAIRE

An interim report on the questionnaire returns was presented by Lieutenant Colonel Lueth. It is expected that during September and October an adequately representative number of returns will be received, and a full report can be presented at the next meeting of the committee on October 28. The returns thus far received indicate that the first sampling of 1,000 presents a characteristic picture and thus has served well the purpose of a specimen or trial sampling.

REPORT ON EDUCATIONAL FACILITIES

Dr. Victor Johnson presented the material of a report on educational facilities required for returning medical officers, which he has prepared with Dr. F. H. Arestad. After considerable discussion of the statistics and comment offered by Dr. Johnson, it was voted that the chairman be authorized to appoint a committee to confer with the Surgeons General regarding places for study in the hospitals of the Army, Navy and civilian hospitals. The chairman designated Dr. Palmer, Dr. Johnson, Lieutenant Colonel Lueth and Father Schwitalla and, as chairman, Dr. Frederick A. Collier.

PROVISIONS FOR LICENSURE OF RETURNING OFFICERS

There appeared before the committee Dr. Barton of the Procurement and Assignment Service, Mr. Wheaton of the War Man Power Commission, Mr. Robinson of the Council of State Agencies and Mrs. Gallaher of the Department of Justice to solicit opinion on a proposal relating to the amendment of the medical practices acts of the states by adding the following:

"If an applicant presents evidence satisfactory to the board that he (1) has been graduated by a medical school reputable and in good standing as determined by the board, has been licensed by a state of the United States, (2) has served in the active military or naval service on or after Sept. 16, 1940 and prior to the termination of the present war as a commissioned medical officer of the Army or Navy and has been discharged or released therefrom under conditions other than dishonorable or has rendered medical service during the period 1940 to 1945 in industry or in a civilian community and (3) is of good moral character, the board in its discretion may issue him a temporary license for a period of time to be fixed in the license issued to practice medicine in this state without requiring that he pass any examination (including a basic science examination if that is a condition precedent to licensure) that otherwise he would be required to pass. An application for such a license shall be on a form approved by the board and shall be accompanied by such fee as is required for other licenses issued without examination."

This amendment is to become effective at once and is to remain in effect until the governor, on the recommendation of the state board of medical licensure, proclaims that this amendment is no longer necessary.

After discussion, the following resolutions were passed unanimously by the committee:

1. That the Committee on Postwar Planning announces its approval of the proposed legislation;

2. That the committee recommends that the Council of State Governments be requested to give active support to the proposed legislation in the various states;

3. That the committee recommends to state medical associations that they support such legislation and that such associations obtain the assistance of the Procurement and Assignment Service of the War Manpower Commission through its state representatives, and

4. That the committee recommends to state medical associations that they appoint liaison officers to correlate the efforts of those supporting this legislation.

ASSISTANCE TO MEN DISCHARGED FROM SERVICE

The chairman then asked Dr. Charles M. Griffith of the Veterans Administration to comment on public law 346, 78th Congress, relating to the provision of educational assistance to men after discharge from military service, since the interpretations and application of this law will be for the Veterans Administration to make. It was voted that the chairman appoint a subcommittee to confer and cooperate with the Veterans Administration, and for this purpose the chairman designated Dr. Collier, Dr. Palmer and Father Schwitalla.

RECOMMENDATIONS ON SURPLUS SUPPLIES

Dr. Palmer reported that a committee of the National Research Council appointed to advise the War Production Board on the subject of essential drugs and supplies had prepared a series of recommendations which cover the measures to be taken in control of the disposal of surplus drugs, materials and supplies after the war. Dr. Palmer stated that the report is now in the committee stage of discussion by Congress but that it would be appropriate for some formulation of opinion to be expressed at this time.

It was voted that the recommendations in the report of this National Research Council committee be approved.

ORGANIZATION OF INFORMATION BUREAU

Dr. West reported that arrangements are being made for the organization of the Information Bureau at American Medical Association Headquarters as authorized by the Trustees of the American Medical Association.

WARTIME GRADUATE MEETINGS

In the absence of Commander Bortz, Dr. Borzell gave an account of the work of the Committee on Wartime Graduate Medical Meetings and requested an expression regarding its continuance after the cessation of hostilities, especially in the European theater of war. It was voted that the committee express its appreciation of the valuable work done under the direction of Commander Bortz and that a further report be requested at the next meeting of the committee.

October 28 was agreed on as being the time for the next meeting of the committee and the place Chicago.

ANNUAL CONFERENCE OF STATE SECRETARIES AND EDITORS

The Annual Conference of Secretaries of Constituent State Medical Associations and Editors of State Medical Journals will be held in Chicago at the offices of the American Medical Association on Friday and Saturday, November 17 and 18. Two sessions of the conference will be held on Friday, November 17, the first at 10 a. m. and the second on the afternoon of that day. On the evening of November 17 a program given over to the discussion of topics of particular interest to editors of the journals of constituent state medical associations will be presented at the Palmer House. The concluding session of the conference will be held at the offices of the Association on the morning of Saturday, November 18.

While these annual conferences have each year been attended by nearly all of the secretaries of constituent state medical associations and editors of medical journals of those associations, there has been a constantly increasing attendance of other officers of constituent state medical associations and officers of component county and district medical societies, and of late

years a very considerable number of members who do not occupy official positions have been present. The members of all those groups will be cordially welcome at the November conference.

All who expect to attend the conference this year are especially urged at the earliest possible time to make necessary arrangements for hotel accommodations and railroad transportation.

WASHINGTON OFFICE BEGINS ACTIVITY

On September 1 the Washington office of the Council on Medical Service of the American Medical Association began its activities. The office is located at 1835 I Street N.W. Dr. Joseph S. Lawrence, formerly representing the Medical Society of the State of New York in Albany, is in charge of this office. Any requests for assistance in relation to material available in Washington may be addressed directly to Dr. Lawrence. The activities of the office will be reported from time to time in THE JOURNAL.

AIR CONDITIONING

The Association's Committee to Study Air Conditioning maintains a compilation of pertinent bibliographic material with brief abstracts related to air conditioning for human comfort and health but not for industrial materials and products.

While this committee cannot undertake to furnish complete bibliographic material, it will furnish, without cost, to physicians and other professional personnel citations with minor abstracts on any one or any small number of the categories mentioned. This committee does not agree to pass on the merits of any air conditioning installation, nor can it furnish detailed plans for desired air conditioning in any operation. The material available is limited solely to citations to the world's literature on air conditioning in relation to human beings such as is available to the committee for review. Abstracting for the years 1942-1943 has just been completed.

The members of the Committee to Study Air Conditioning are Alvan L. Barach, Walter M. Simpson, C. P. Yaglou and Carey P. McCord, Chairman. Requests should be addressed to Carey P. McCord, M.D., 10 Peterboro Street, Detroit 1, Michigan.

This material is segregated in the following categories:

Air Analysis.	Hospital Air Conditioning.
Air Cleaning.	Hotels.
Air Conditioning in Tropics.	Humidity, Humidifying and Dehumidification.
Aircraft.	Industrial Air Conditioning and Ventilation.
Air Flow, Air Circulation and Distribution, Air Movement.	Instruments and Apparatus, Laboratory.
Air Pressure, High.	Insulation.
Air Raid Shelters and Military Air Conditioning.	Ionization.
Allergy and Allergens.	Laws, Standards and Codes.
Altitudes, High, Low Air Pressure.	Libraries and Museums.
Apparatus Breathing.	Mines.
Bacteria.	Miscellaneous Buildings and Structures.
Banks.	Natural Infiltration.
Charts and Tables.	Newspapers.
Climate, Season and Weather.	Noise and Noise Control.
Clothing.	Odors and Odor Effects, Air Freshness, Deodorization.
Comfort and Comfort Zone.	Office Buildings.
Condensation.	Operating Rooms (Hospitals).
Cooling Agents for Air Conditioning Refrigerants, General.	Oxygen and Oxygen Therapy.
Cooling and Refrigeration, Summer Cooling.	Ozone.
Costs, Economics and Sales.	Personal Protective Equipment.
Dehydration.	Physical and Physiologic Principles, General.
Department Stores, Stores.	Pollution, Atmospheric, General.
Design.	Priorities and Rationing.
Ducts.	Progress and Future of Air Conditioning.
Dust Control.	Public Buildings.
Dust Determinations.	Railroads and Automobiles.
Education and Training.	Respiratory Diseases.
Environment and Health.	Restaurants.
Equipment.	Schools.
Fans.	Ships.
Fire Hazards.	Sterilization of Air.
Heat.	Temperature and Humidity Control.
Heat Regulation (Temperature Regulation).	Temperature Changes.
Heat Transfer.	Temperature, Effective.
Heating and Ventilation and Air Conditioning, General.	Tunnels.
Heating, Radiant.	Windowless Structures and Black-outs.
Homes and Apartment Houses.	

WASHINGTON LETTER

(From a Special Correspondent)

Sept. 18, 1944.

Hearings of Pepper Subcommittee on Wartime Health and Education

"Medical care for the people of the United States is not enough," Dr. Roger I. Lee, President-Elect of the American Medical Association and chairman of the Joint Committee on Postwar Medical Service, told the Pepper hearings on wartime health and education here. "It must be good medical care. Good medical care is based on good medical education, on medical research and on good medical communication." Dr. Lee declared that no doctor who graduated ten years ago can be a good practitioner solely on what he learned in medical school. Continuing medical education for the doctor is necessary, to be met only partly for most doctors by reading, perhaps by medical meetings, by long or short courses, or by long or short visits to medical centers and hospitals. "It is customary and accurate to state that the United States has the finest health record in the world. But that is not enough," he continued. "The practice of medicine in the United States is undergoing rapid change. We live in a changing world," Dr. Lee said. "Good roads, airplanes and other new devices will have a part in the changes in our lives and medical practice. Controlled scientific experimentation can, I think, be depended on to develop sound medical care for every one in the United States. This will require the cooperation of the government, the medical profession and the public."

On the subject of prepayment medical plans, Dr. Lee said some had been discarded as unsound, others had "folded up" as unsuccessful. While the insurance principle had a definite appeal, there were difficulties in its application. The insurance principle seemed to be working fairly but not altogether successfully in voluntary prepayment hospitalization plans. General prepayment sickness plans had similar success when the insured group was homogeneous, as in some industries or universities. General plans, he said, found great difficulties in the heterogeneous population of the country. Great Britain's national health insurance plan, so often quoted, has met great difficulties and has not resulted in furnishing medical service approaching the quality of medical care in the United States. Maintenance of the quality of medical care is fundamental in any health program, he said, declaring it was hard to improve the phraseology of a British recommendation: "There should be initiated, by arrangement and agreement between the government and the profession, organized experiments in the methods of practice, such a group practice, including health centers of different kinds, which should extend to general practitioners hospital units attached to general hospitals. Future developments in group practice should depend on the results of such clinical and administrative experimentation."

Dr. Lee elaborated on the report that 4,000,000 men had been rejected as physically disqualified for the armed forces. Standards of physical fitness had varied as the needs for manpower varied. The examinations were carried out by 33,000 physicians and 10,000 dentists who had served without remuneration. Some of the doctors boasted that they were "tough" and their personal interpretation of the standards had been tough, in the belief that all men should be fit for overseas combat service. Other examining doctors were lenient, and some soldiers they had passed were found unfit for training and were discharged. Rejections had been made for mental disease, mental deficiency, illiteracy and neurologic disorders. Dr. Lee felt that many in other categories could be made to meet standards and needs of the armed forces.

Dr. Lee said that to ascertain postwar plans of medical officers a questionnaire had been circulated with enthusiastic consent of the Surgeons General of the Army, Navy and Public Health Service. The Joint Committee was amazed at the large response and uniformity of answers to the questionnaire. Younger officers largely wanted to finish or supplement their training, older men wanted to get back to their practices, although some wanted short refresher courses. The Joint Committee, Dr. Lee said, was greatly concerned in the problem of disposal of surplus war supplies as they concern medical and hospital supplies.

Many returning medical officers will find their medical equipment obsolete or dissipated. Hospitals, having yielded to needs of the armed forces, require x-ray machines, surgical instruments, rubber gloves, and other supplies.

First witnesses at the resumed sessions of the Pepper Subcommittee on Wartime Health and Education were Dr. R. L. Sensenich of the Board of Trustees, American Medical Association, Dr. Harvey Stone, member of the Council on Medical Education and Hospitals, and Dr. Lee. Dr. Stone further elaborated on the reason for rejection of a large number of draftees by the various examining bodies functioning under the Selective Service law. The rejections had attracted wide attention and led to inferences and deductions that general public health was in a deplorable state. "I believe that a careful appraisal of the facts do not warrant the drawing of such conclusions," he said. Dr. Stone said that, despite the withdrawal of about 55,000 doctors into the federal services through the war, a general breakdown of civilian medical care had not resulted. "This remarkably good record shows that, despite shortages in trained personnel, the public health services, such as the protection of the food and water supply, the maintenance of sanitary conditions, control of infectious diseases and, more particularly, the care of the sick, are still operating efficiently," he said. Dr. Stone recommended a change in the attitude of Selective Service to assure a continuous supply of medical school graduates. He also saw benefits accruing from a well thought out and soundly organized program for hospital and laboratory facilities in areas now inadequately supplied.

Hearing on the Physically Handicapped

American Medical Association statistics on the number of hard of hearing persons in the United States were submitted to the Kelley hearing on the Physically Handicapped here this week. Alan B. Crammatte of the American Federation of Physically Handicapped, Inc., quoted the figures showing an overall total of some 5,500,000 deaf persons, with about 3,000,000 children affected in some degree and between 60,000 and 100,000 totally deaf. Mr. Crammatte was one of several witnesses who charged that educational facilities for deaf and hard of hearing children in the country are wholly inadequate both in teaching personnel and in equipment.

The American Medical Association was to have been represented at the hearings by Dr. Walter Hingston, director of the Abington (Pa.) Memorial Hospital, but Dr. Hingston was taken seriously ill in Washington and was unable to attend

the sessions. Two medical witnesses were Dr. Harry Best of the University of Kentucky, Lexington; author of books on the subject, and Dr. Robert West, professor of speech pathology, University of Wisconsin, Madison. While Dr. Best's testimony did not touch to a great extent on the medical aspects of the question, he expressed pleasure that the federal government was taking an interest in the welfare of the deaf. Employers generally were unaware of what the deaf can do. He advocated more publicity and proposed that each state have a person to advise the deaf and employers alike, to their mutual advantage. Dr. Best expressed the opinion that there are 5 deaf per 10,000 in the country on the basis of census reports. He said that 60 per cent of the afflicted are congenitally deaf, 27 per cent are deaf before 3 years of age and 13 per cent later. Deafness, he indicated, was a problem both of childhood and of old age. He reported Wisconsin plans to set up centers in the state where the hearing loss of each individual will be estimated and help will be given in selecting a hearing aid.

Criticism of the federal government employment policies in regard to deaf and hard of hearing elicited an official statement from the Civil Service Commission that it had surveyed 3,500 types of jobs and found that 1,200 of them could be handled by totally deaf persons and 3,200 by hard of hearing. The commission reported that since October 1942 the government had hired 3,000 hard of hearing and 1,500 totally deaf persons.

Among witnesses at the hearings for the deaf were Miss Elizabeth Withers, American Occupational Therapy Association, Washington; Edmond Boatner, American School for the Deaf, West Hartford, Conn.; Ben M. Showe, National Association of the Deaf; Raymond H. Greenman, managing director, American Society for the Hard of Hearing; Miss Josephine Timberlake, executive secretary, Volta Bureau; Paul A. Strachan, president, American Federation of the Physically Handicapped, and Rev. Herbert C. Merrill, president, Gallaudet College Alumni Association.

Representative Augustine B. Kelley (Democrat, Pennsylvania) reported that further hearings of his committee on the physically handicapped will be held in New York on October 2-4, in Pittsburgh on October 17 and 18 and in Detroit on October 19 and 20. Mr. Kelley has expressed to Dr. Olin West, Secretary of the American Medical Association, his gratitude for cooperation rendered in the hearings by the American Medical Association and for publicity in *THE JOURNAL*, which he said had resulted in valuable material being sent directly to the committee.

MEDICAL ECONOMIC ABSTRACTS

ANOTHER COMPULSORY SICKNESS INSURANCE PLAN

The Subcommittee on Medical Care of the Committee on Administrative Practice of the American Public Health Association has submitted a "preliminary report" on the national program for medical care. This report appears in the September 1944 issue of the *American Journal of Public Health* (p. 984). The program suggested follows closely the recommendations of the International Labor Organization on Sickness Insurance already described in *THE JOURNAL*.¹

The similarity is shown in the following selection from the preliminary report of the Subcommittee on Medical Care:

A national program for medical care should make available to the entire population, regardless of the financial means of the individual, curative services.

Services should be adequately and securely financed through social insurance supplemented by general taxation, or by general taxation alone.

The public health agencies—federal, state and local—should carry major responsibilities in administering the health services of the future.

The agency authorized to administer such a program should have the advice and counsel of a body representing the professions, other sources of service and the recipients of services.

There is more of a similarity to the Wagner-Murray-Dingell bill than is found in the original recommendations of the International Labor Office in that the public health department is

proposed as the administrative agency and that the role of the medical profession is reduced to representation in an advisory commission.

The members of the subcommittee submitting the report are Joseph W. Mountin, M.D., chairman, Earle G. Brown, M.D., David D. Carr, M.D., Edwin F. Daily, M.D., Graham Davis, I. S. Falk, Ph.D., J. Roy Hege, M.D., Hugh R. Leavell, M.D., Emory Morris, D.D.S., George St. J. Perrott, Marion G. Randall, R.N., Edward S. Rogers, M.D., and Nathan Sinal, D.P.H.

PROGRESS OF MEDICAL SERVICE PLANS

Medical-Surgical Plan of New Jersey.—The first contracts were issued in July 1942. It serves the state of New Jersey and offers both medical and surgical contracts. On Dec. 31, 1943 it had a total membership of 7,334 males and 8,681 females, including both subscribers and dependents. During 1943 it had an income from subscribers of \$74,498.47, expended \$67,348.46 and accumulated a surplus of \$12,201.35.

California Physicians' Service.—This was organized in 1939 and serves the state of California. On March 31, 1944 it had contracts covering 38,990 males and 53,010 females, making a total of 92,000. Its income to the date mentioned was \$1,280,054.03; disbursements amounted to \$1,206,401.39, leaving a net gain of \$73,652.64. It now has a stabilization fund of \$90,165.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. Frank M. Hall has resigned as director of the Limestone County Health Unit in Athens to organize a similar unit in Gainesville, Fla., it is reported.

Condemnation Proceedings Started for Medical School Site.—Condemnation proceedings have been started on four square blocks between Sixth and Eighth avenues, south, and Eighteenth and Twentieth streets, Birmingham, to provide a site for the new University of Alabama School of Medicine (THE JOURNAL, March 4, p. 658, and April 22, p. 1212). Plans are under consideration to merge Hillman and Jefferson hospitals under the Jefferson Hospital roof, which would leave Hillman Hospital vacant. Tentative plans include using the vacant building as temporary administrative offices for the four year medical school.

CALIFORNIA

Fund for Tropical Medicine.—The Columbia Foundation of San Francisco has given \$13,800 to assist in the establishment of a department of tropical medicine at the University of California Medical School, San Francisco, it is reported.

Tuberculosis Control in the State Hospitals.—The state department of public health is cooperating with the state department of institutions in a program of tuberculosis case finding in state hospitals. A mobile x-ray unit will be used in the project. X-ray examinations have already been completed of most of the patients in Patton State Hospital, Patton. A similar program will be undertaken in the Folsom State Prison, which, according to *California's Health*, will be the first tuberculosis x-ray survey of a California state prison.

Medicine to Benefit in Appropriations for Postwar Planning.—More than \$27,000,000 will be expended by the University of California in a building program to be undertaken after the war. The legislature has already appropriated several million dollars for the work, which includes new buildings and expansion programs for medical and public health projects. At Los Angeles the proposed projects will include the student health center, \$450,000; student hospital, \$600,000. life sciences, \$1,000,000. In San Francisco more than \$6,000,000 will be spent, \$4,000,000 to finance a teaching hospital, \$1,000,000 for medical science, \$500,000 for a nurses' home, \$200,000 for interns' quarters and \$100,000 for a dental clinic.

DISTRICT OF COLUMBIA

Annual Scientific Assembly.—The Medical Society of the District of Columbia will hold its annual scientific assembly at the Mayflower Hotel, Washington, October 5-7, under the presidency of Dr. Fred R. Sanderson. The program is presented as a preview of postwar medicine and includes the following speakers:

Dr. Robert H. Williams, Boston, Thyrotoxic Treatment of Thyrotoxicosis.
Dr. Lothar B. Kalinowsky, New York, Electric Convulsive Therapy in Psychoneuroses.
Lieut. Howard M. Odel (MC), The Future of Our Coronaries.
Louis L. Williams Jr., medical director, U. S. Public Health Service, The Malaria Problem.
Dr. Howard F. Root, Boston, Diabetes Tomorrow.
Dr. Frank H. Lahey, Boston, Biliary Tract Surgery.
Lieuts. C. Hunter Shelden and Robert H. Pudenz (MC) and Lieut. Comdr. Joseph S. Restarski (DC), Direct Observation of the Brain Under Physiologic Conditions.
Dr. George P. Muller, Philadelphia, Regional Ileitis.
Dr. James Ross Veal, Management of Venous Thrombosis.
Comdr. George W. Christensen (DC), Oral and Plastic Surgery.
Brig. Gen. Fred W. Rankin, M. C., Surgery in the Forward Echelon.
Brig. John Tilden Howard and Arthur M. Skingley, Baltimore, Inflammatory Lesions of the Lower Gastrointestinal Tract.
Dr. Frank E. Adair, New York, Cancer of the Breast.
Lieut. Comdr. Francis S. Cheever (MC), The Dysenteries.
Lieut. Comdr. Kirby, Surgeon General of the Army, Present Concepts of Military Surgery as Developed in the European Theater.
Dr. Frank W. Konzelmann, Philadelphia, Recent Advances in Laboratory Diagnosis.
Dr. Norman M. Scott, Trenton, N. J., Experiments in Medical Care.
Major Charles R. Brooke, M. C., Rehabilitation of Veterans.
Col. Leonard G. Rowntree, M. C., The National Program for Physical Fitness.
Major Henry B. Gwynn, M. C., Reconditioning in Civilian Hospitals.
Dr. Geza de Takats, Chicago, The Causalgic State in Peace and War.

Luncheon sessions during the meeting will be addressed by Commodore Arthur W. Clarke of the Royal Navy, who will speak on "Maintaining Morale in Fighting Men at Sea"; Major Gen. David N. W. Grant, the Air Surgeon, "Aviation Preventive Medicine," and William Mather Lewis, LL.D., president of Lafayette College, Easton, Pa. One feature will include a panel discussion on chemotherapeutic drugs with the following speakers: Dr. Chester S. Keefer, Boston, moderator; Lieut. Col. Michael E. DeBakey, M. C., Lieut. Comdr. Adolph M. Hutter (MC) and Lieut. Comdr. Edwin E. Barksdale (MC). There will be a panel discussion Saturday morning on the future of medicine with the following speakers: Dr. John P. Peters, New Haven, Conn.; Dr. Walter H. Judd, congressman from Minnesota; Ross T. McIntire, Surgeon General of the Navy; Claude D. Pepper, Senator from Florida; Thomas Parran, Surgeon General of the Public Health Service, and Dr. John H. Fitzgibbon, Portland, Ore.

INDIANA

Fellowship in Cancer.—Establishment at the Robert W. Long Hospital of the Indiana University Medical Center, Indianapolis, of a fellowship for the training of a pathologist in specialized diagnoses and research in cancer has been announced by the Indiana Women's Field Army of the American Society for the Control of Cancer. The Women's Field Army of Marion County, assisted by the state division, will provide also during the coming year for the sponsorship of the services of Miss Millicent Duckworth, medical center research worker, in the follow-up of cancer patients in the medical center and Indianapolis City Hospital clinics.

State Medical Meeting.—The ninety-fifth annual meeting of the Indiana State Medical Association, in conjunction with the army air force medical services, will be held at the Murat Temple, Indianapolis, October 3-5, under the presidency of Dr. Jacob T. Oliphant, Farmersburg. Among the speakers will be:

Dr. Paul H. Holinger, Chicago, Bronchoscopic Diagnosis of Bronchial Tumors.
Dr. Lillian B. Mueller, The Teaching of Anesthesia.
Major Gen. David N. W. Grant, the Air Surgeon, Medical Aspects of Pressurized Aircraft.
Dr. Newell C. Gilbert, Chicago, Functional Disturbances versus Organic Heart Disease.
Dr. Chester S. Keefer, Boston, Indications and Methods of Use of Penicillin.
Dr. Virgil S. Conneller, Rochester, Minn., Indications for Radical versus Conservative Treatment for Gynecologic Conditions.
Colonel Howard A. Rusk, M. C., New Horizons in Management of Convalescents.
Brig. Gen. Fred W. Rankin, M. C., Advances in Army Medicine.
Ross T. McIntire, Surgeon General of the Navy, Medical Aspects of Naval Warfare.
Dr. A. Jerome Sparks, Fort Wayne, Upper Urinary Tract Symptoms of General Interest.
Major Randolph L. Clark Jr., M. C., The Evolution of the Treatment of Pilonidal Cysts in Sinuses.
Dr. Eugene B. Mumford, Indianapolis, Bone Grafts—Review of 193 Cases.
Dr. Leo K. Cooper, Gary, Surgery of Trauma and Its Importance as an Emergency.
Major Dillon D. Geiger, M. C., Penicillin in Otolaryngology.
Major John G. Bellows, M. C., Penicillin in Ophthalmology.
Dr. Ralph M. Waters, Madison, Wis., Artificial Respiration.
Major Donald S. Thateber, M. C., The Correction of Protein Deficiency by Amino Acid Therapy in the Management of Surgical Patients.
Dr. Charles N. Combs, Terre Haute, The First Nitrous Oxide Anesthesia Administered by Dr. Horace Wells, Dec. 11, 1844—A Memorial.

At the annual banquet, Dr. Frank H. Lahey, Boston, will discuss "Present and Postwar Medical Economic Problems." The program also includes Michael "Mickey" MacDougall, New York, on "Card Sharks versus Soldiers and Sailors."

MICHIGAN

Physicians Honored.—The Lapeer County Medical Society gave a dinner August 29 in honor of physicians who have completed fifty or more years in the practice of medicine. Among the guests were Dr. Frank A. Timber, Lapeer, who has served sixty years, and Drs. David H. Burley, Almont, and Henry G. Merz, Lapeer, both of whom have completed fifty years in the practice of medicine.

Changes in Health Personnel.—Dr. Louis K. Peck has been appointed health officer of Crawford, Kalkaska, Missaukee and Roscommon counties with headquarters in Lake City. —Dr. Douglas S. Fryer resigned August 11 as assistant director of the bureau of local health services, Michigan Department of Health, Lansing, to join the Wyeth Laboratories, Philadelphia. —Dr. William A. Corcoran has been appointed health officer of Ishpeming, succeeding Dr. Neal J. McCann (THE JOURNAL, August 26, p. 1193).

Postgraduate Medical Conference.—On October 13 the University of Michigan Medical School, Ann Arbor, will conduct its annual postgraduate medical conference. Among the speakers will be

Dr Sture A. M. Johnson, Nev. of the Skin, Diagnosis and Treatment
Dr Gordon K. Moe, Circulatory Actions of the Veratrum
Dr Carl D. Camp, Postural Tension as a Cause of Pain
Dr Albert C. Furstenberg, Diseases of the Salivary Glands
Dr Cyrus C. Sturgis, Medical Treatment of Diseases of the Thyroid Gland
Dr Frederick A. Collier, Surgical Treatment of Diseases of the Thyroid Gland
Dr John Alexander, The Management of Benign and Malignant Interthoracic Neoplasms
Dr Raymond W. Waggoner, Psychiatric Aspects of Chest Pain
Dr Norman F. Miller, Toxemias of Late Pregnancy

MISSOURI

Annual Fall Clinical Conference.—The twenty-second annual fall clinical conference of the Kansas City Southwest Clinical Society will be held in Kansas City, October 24, at the Municipal Auditorium. Dr Max Goldman, Kansas City, president of the southwest clinical society, will give the address of welcome. Among the speakers will be

Dr Frederic E. B. Foley, St. Paul, Management of Vesical Neck Obstruction
Dr Russell L. Haden, Cleveland, Treatment of Rheumatoid Arthritis
Dr Robert L. Jackson, Iowa City, The Management of Acute Rheumatic Fever in Children
Dr Frank H. Lahey, Boston, The Management of Surgical Lesions of the Terminal Ileum, Colon and Rectum
Capt Bruce V. Leamer (MC), Aviation Medicine—A Brief Review and Its Part in the Present War
Dr William F. Rienhoff Jr., Baltimore, Surgical Treatment of Lesions of the Biliary Tract
Dr Earl C. Sage, Omaha, Questions Arising in the Office Practice of Obstetrics and Gynecology
Dr Cyrus C. Sturgis, Ann Arbor, Mich., The Leukemias
Dr Owen H. Wangenstein, Minneapolis, Studies on the Origin and Treatment of Ulcer

The guest speakers are scheduled for more than one topic for discussion. "The Newer Things in Medicine" will be considered in a round table discussion conducted by Dr Ira H. Lockwood, Kansas City, Dr Foley, Dr Haden, Dr Rienhoff, Dr Sturgis and Dr Wangenstein. At a joint evening session with the local county medical societies on Tuesday Dr Lahey will discuss "Medicine Today, In and Out of the Service and After the War." The program also includes symposiums on gastroenterology, obstetrics, pediatrics, cardiovascular diseases, urogenital abnormalities and headache and backache.

NEW YORK

Commission Named to Study Care of Needy.—Dr Basil C. MacLean, medical director of the Strong Memorial Hospital, Rochester, has been appointed head of a ten member commission requested by Governor Dewey to draft a program providing medical care for needy persons in the state, according to the Rochester *Democrat and Chronicle*, September 7. The commission, which has \$40,000 for its work, was authorized by the 1943 legislature and results of its study are intended for use in formulating legislation for submission in 1945. The commission will make necessary studies to devise programs for medical care for persons of all groups and classes in the state of New York. Governor Dewey is reported to have said in a press interview. "The commission was created after Governor Dewey told the legislature in his annual message last January that medical care for persons who cannot provide it for themselves was 'one of the chief areas of unmet human need'." Assemblyman Lee B. Mailler, sponsor of the bill, was designated by the governor as vice chairman of the group, although he is also an ex officio member. Other members of the commission include Dr George M. Mackenzie, Cooperstown, Dr Heiman G. Weiskotten, Syracuse, Dr Lucien M. Brown, Rev. John J. Bingham, Dr Robert L. Levy and Garrard B. Winston, lawyer, all of New York City, Miss Ruth Hall, R.N., Buffalo, Miss Agnes Gelinas, R.N., New York, and Miss Marion W. Sheahan, R.N., Albany.

New York City

Cancer Foundation Seeks Funds.—On September 4 the National Foundation for the Care of the Advanced Cancer Patients Inc., opened a campaign to raise \$1,800,000 to provide beds and care in established institutions at low cost for incurable cancer patients. The campaign will be carried out under the direction of the foundation's executive committee, consisting of Julius J. Perlmutter, president, Dr Frank E. Adair, president of the American Society for the Control of Cancer, Dr Roscoe R. Spencer, director of the National Cancer Institute, Bethesda, Md., John W. Wingate of New York University, Morris M. Bernstein, treasurer, Morton Morrison, secretary of the foundation, and Mrs. Francis J. Rigney,

commander of the Metropolitan area of the Women's Field Army of the New York City Cancer Committee. Organization of the foundation was announced in THE JOURNAL, May 20, page 221.

New Psychosomatic Clinic.—A psychoanalytic and psychosomatic clinic for training and research has been established in the department of psychiatry at Columbia University College of Physicians and Surgeons. The new clinic, said to be the first of its kind in the United States, is under the supervision of Dr. Nolan D. C. Lewis, executive officer of the department of psychiatry at Columbia University and director of the New York State Psychiatric Institute and Hospital. Dr. George E. Daniels, clinical professor of psychiatry, has been appointed chief of the psychosomatic service. The following additional appointments were announced: Dr. Sandor Rado, clinical professor of psychiatry, director of the clinic and chief of the psychoanalytic services for inpatients and outpatients; Dr. David M. Levy, assistant clinical professor of psychiatry and chief of the psychoanalytic service for children; Dr. Abraham Kardiner, assistant clinical professor of psychiatry and chairman of the seminar on comparative analysis of cultures. The new clinic is located at the Columbia-Presbyterian Medical Center and will be opened in October. Qualified physicians who are graduates of an approved medical school and have completed an approved hospital internship of not less than one year will be required to undergo a psychoanalysis in order to be admitted to the three year course of resident graduate training in psychoanalysis and psychosomatic medicine. The course of training includes a systematic program of lectures and seminars, clinical conferences and supervised clinical work on the psychoanalytic and psychosomatic services. It is combined with two years of resident graduate study in the other branches of psychiatry, with emphasis on the related basic medical sciences. Those who meet the requirements may register for the degree of doctor of medical science. On completion of an acceptable, original and previously unpublished dissertation on the laboratory or clinical aspects of the specialty and satisfactory completion of written, oral and practical examinations in related clinical and laboratory fields, the candidate may be recommended for the degree of doctor of medical science.

OHIO

Medical Society Observes Centennial.—The one hundredth anniversary of the Northwestern Ohio Medical Society will be held at the Elks Club, Findlay, October 3. A luncheon address will be delivered by Dr. Walter C. Alvarez, Rochester, Minn., on "Hints in the Recognition of Puzzling Abdominal Pain." Other speakers, members of the faculty of the University of Cincinnati College of Medicine, will be

Dr. Marion A. Blankenhorn, The Toxic Reactions of the Newer Sulfonamides
Dr. A. Ashley Weech, The Child Who Won't Eat
Dr. Joseph A. Freiberg, Some Common Foot Disabilities in Children and Adults
Dr. Leon Schiff, Tests of Liver Functions in Health and in Disease
Dr. William A. Altmeier, Penicillin: The Management of Surgical Infections

Dr. Wayland B. Recker, Leipsic, is president of the society and Dr. John M. Leahy, Tiffin, secretary.

Industrial Disbursements.—The Industrial Commission of Ohio disbursed \$3,457,727.45 for medical services to injured Ohio workmen during 1943, according to the *Ohio State Medical Journal*. This figure includes a relatively small amount for dental services. Other expenditures during the year included \$1,801,325, hospital care and nursing, \$130,821.34, funeral expenses, and \$97,001.18 court costs, a total of \$5,486,874.97. These amounts include payments covering treatment of injured private and public employees as well as similar costs on occupational diseases and are in addition to death awards and compensation to injured workmen. Comparative figures for 1942 were \$4,243,069.09 for medical services, \$1,760,898.69 for hospital care and nursing, \$133,104.41 for funeral expenses and \$86,661.34 for court costs, a total of \$6,223,733.53. The considerable decrease in 1943 of the amount disbursed for medical service is of no special significance, as a change by the auditing department of the Industrial Commission in the method of compiling records in 1942 resulted in the inclusion in the 1942 figure of approximately \$800,000 of medical fees which had been allowed late in 1941 but were actually paid in 1942. The amount disbursed by the commission for medical service during 1941 was \$3,322,792.06. The number of claims filed during 1943 was 331,072, a record for the thirty-two year history of the Ohio Workmen's Compensation Fund. There were 320,793 claims filed in 1942, the previous peak year. The total for 1932, during the depression, was 130,099. Medical only claims involving payment for physicians' services but no compensation to the claimant for loss of time, num-

bered 260,150 in 1943, or 78.6 per cent of all claims filed, compared with 80 per cent in 1942. The average fee of "medical only" claims increased from \$7.69 in 1942 to \$7.88 in 1943.

PENNSYLVANIA

Philadelphia

Another Cancer Prevention Clinic.—On August 10 the International Cancer Research Foundation sponsored the opening of a cancer prevention clinic at the Jeanes Hospital, Fox Chase, under the direction of Dr. Elizabeth W. F. Love, medical director, and Dr. Hoke Wammock, medical chief of staff. This is the sixth of these clinics operating in Philadelphia at the present time (*THE JOURNAL*, August 26, p. 1200).

Changes at Woman's Medical College.—Recent changes on the faculty of the Woman's Medical College of Pennsylvania include the following appointments:

James O. Brown, Ph.D., to associate professor of anatomy and acting head of the department.
Dr. Ruth Harley Weaver to acting associate professor of preventive medicine.

Dr. Francis H. Murray to clinical assistant professor of proctology.
Dr. Mary E. McKee Porter to assistant director of the clinical laboratory.

Promotions on the faculty include:

Gina Castelnovo, Ph.D., to assistant professor of anatomy.
Dr. Helen M. Angelucci to clinical associate professor of gynecology.
Dr. Laura E. McClure to clinical associate professor of pediatrics.
Dr. Harriet M. Felton to clinical assistant professor of pediatrics.

UTAH

State Medical Election.—Dr. Ray T. Woolsey, Salt Lake City, was chosen president-elect of the Utah State Medical Association at its recent meeting in Salt Lake City, August 24, and Dr. Ezekiel R. Dumke, Ogden, was installed as president. Drs. Roy W. Robinson, Kenilworth, Horace Asa Dewey, Richfield, and John P. Burgess, Hyrum, were chosen vice presidents; Dr. David G. Edmunds, Salt Lake City, constitutional secretary, and Dr. Hyrum R. Reichman, Salt Lake City, treasurer. Dr. David P. Whitmore, Roosevelt, was named honorary president; Mr. W. H. Tibbals, Salt Lake City, was reelected executive secretary of the association. The 1945 meeting will be held in Ogden.

GENERAL

American Pediatric Society.—The fifty-fifth annual meeting of the American Pediatric Society will be held at the Hotel Claridge, Atlantic City, N. J., September 26-27, under the presidency of Dr. James L. Gamble, Boston. Included among the speakers will be:

Dr. William L. Bradford, Rochester, N. Y., Effectiveness of Sulfadiazine and Antipertussis Serum in the Treatment of Pertussis
Dr. Stewart H. Clifford, Brookline, Mass., Clinical Significance of Yellow Straining of the Venuis Caeosa, Skin and Umbilical Cord in the Newborn
Dr. Harriet G. Guild, Baltimore, Acute Idiopathic Porphyria with Repeated Attacks of Peripheral Neuritis: Treatment with Liver Extract
Dr. Josef Warkany and Elizabeth Schraffenberger, Cincinnati, Congenital Malformations of Ears Induced by Maternal Vitamin A Deficiency
Dr. Daniel C. Darrow, Hamden, Conn., Intestinal Alkalosis
Dr. Sidney Farber, Boston, Nature of Some Diseases Ascribed to Disorders of Lipid Metabolism
Dr. Arild E. Hansen and Hilda F. Wiese, Ph.D., Minneapolis, Clinical and Lipid Studies on Child with Chylous Ascites
Drs. L. Emmett Holt Jr. and Victor A. Najjar, Baltimore, Bio-synthesis of Vitamins in Man
Dr. Laslo Kajdi, Baltimore, Comparison of the Effect of Vitamin D and Citrates on Mineral Metabolism in Late Rickets
Drs. Benjamin Kramer and Benjamin Phillips, Brooklyn, Chemotherapy of Staphylococcus Aureus Infections in Infants
Dr. Charles A. Weymuller, Brooklyn, Use of Sulfathiazole Ointment for Impetigo in Infants
Drs. Milton Rapoport and Mitchell I. Rubin, Philadelphia, Influence of Sulfonamide Therapy on the Course of Acute Glomerulonephritis
Dr. Charles Hendee Smith, New York, Self Feeding of Infants
Dr. Julian D. Boyd, Iowa City, Clinical Significance of Head Size of Infants
Dr. Ethel C. Dunham, Washington, D. C., Effect of Rickets in Infancy on the Pelvis in Adolescence
Drs. Donovan J. McCune and Brunhilde Bruch, New York, Basal Metabolism of Children. Further Observations on Obese Children Which Suggest the Superiority of Standard Based on Weight
Dr. Francis F. Schwenker, New York, Type Specific Vaccination Against Streptococcal Infections
Drs. Joseph Stokes Jr. and Tzeze N. Harris, Philadelphia, Three Year Study of the Chemical Applications of Disinfection of Air by Glycol Vapors
Dr. John A. Toomey, Cleveland, Attempts to Isolate Poliovirus in Fish
Dr. Irvine McQuarrie and Mildred R. Ziegler, Ph.D., Minneapolis, Metabolic Studies in a Case of Familial Periodic Paralysis
Dr. Harry Bakwin, New York, Pseudodoxia Pediatrica

On Wednesday there will be a symposium on "Crying of Newly Born Babies: Community Aspects" presented by Dr. C. Anderson Aldrich, Rochester, Minn.; Chieh Sung, Catherine Knop, Geraldine Stevens, R.N., and Margaret Burchell on Wednesday. The meeting Tuesday evening will be a joint session with the Society for Pediatric Research.

American Public Health Association.—The second wartime public health conference and the seventy-third annual business meeting of the American Public Health Association will be held at the Hotel Pennsylvania, New York, October 2-5, under the presidency of Dr. Felix J. Underwood, Jackson, Miss. Laboratory technic, epidemiology, industrial hygiene, school health, food and nutrition, vital statistics, dental health, public health education and maternal and child health will be among the various sessions, and speakers will include:

Major Walter P. Havens Jr., M. C., Dr. Robert Ward and Victor A. Drill, Ph.D., New Haven, Conn., Epidemiologic Studies on Infectious Hepatitis
Howard J. Shaughnessy, Ph.D., and Frances I. Friewer, Chicago, Excretion of Typhoid Bacilli by Carriers: Comparative Value of Fecal and Bile Specimens in Their Detection
S. Edward Silk, Ph.D., Dallas, Texas, The Effect of Environmental Temperature on Experimental Influenza in Mice
Dr. Charles M. Carpenter, Rochester, N. Y., The Development in Virus of Penicillin Faststrains of the Gonococcus
Nathan Sinai, Dr.P.H., Ann Arbor, Mich., Scope, Administration and Financing of a National Health Service
Irene G. Macy Hoosler, Ph.D., Detroit, Implications of Nutrition in the School Health Program
Dr. Milton J. E. Senn, New York, The Influence of Psychologic Factors on the Nutrition of Children
Drs. Guillermo Arbona and Pablo Morales Otero, San Juan, P. R., Public Health in the Tropics

Raymond B. Fosdick, LL.D., New York, will deliver the third annual Delta Omega Lecture Tuesday evening on "Public Health as an International Problem." A special session Wednesday will be devoted to "Today's Global Frontiers in Public Health"; for South America, Major Gen. George C. Dunham, M. C.; for China, Dr. Szeming Sze; for Great Britain, Dr. Melville D. Mackenzie, and for the United States, Thomas Parran, Surgeon General of the Public Health Service. On Thursday morning there will be a demonstration of cooperative effort for health education of workers on the job in New York by:

Dr. Jacob H. Landes, The Plan of the Fort Greene Industrial Health Committee
Louis Hofflander, Cooperation in the Plan
Dr. L. Holland, Cooperation in the Plan
Kenneth D. Wic, Cooperation
Dr. Charles F. McCarty, Organized Medicine's Cooperation
Philip R. Mather, Role of the National Voluntary Agency.

Another session the same day will be devoted to "The Effect of War on Tuberculosis" with the following speakers: Goddard J. Drolet, New York, "World War I and Tuberculosis"; Dr. James A. Doull, Cleveland, "Tuberculosis in England and Other Countries at War"; Mary V. Dempsey, New York, "Current Tuberculosis Statistics in the United States"; Col. Esmond R. Long, M. C., "Tuberculosis in the Armed Forces," and Herman E. Hilleboe, medical director, U. S. Public Health Service, "Small Film Radiography Among Industrial Groups." "Industry versus Venereal Disease" will be the theme of a program sponsored by the American Social Hygiene Association Monday evening, October 2. The session will be presided over by Dr. Victor G. Heiser, Bantam, Conn., consultant, committee on industrial health, National Association of Manufacturers, and speakers will include:

Mr. Reginald E. Gilmor, president, Sperry Gyroscope Company, Long Island, N. Y.
Dr. William L. Weaver, medical director, Du Pont Rayon Plant, Richmond, Va.
Mr. Abraham Bluestein, executive director, Labor League for Human Rights, American Federation of Labor.
Mr. Percy Shostac, consultant on industrial cooperation, American Social Hygiene Association

Other groups meeting during the public health session will include, among others, the American Association of Public Health Dentists, the American School Health Association and the American Society for Research in Psychosomatic Problems.

FOREIGN

Personal.—Dr. Pasteur Vallery Radot, Paris, is the new French minister of health.

Physicians for India.—A program intended to train about 300,000 physicians over a period of about thirty years has been adopted by the health survey and development committee, set up by the government of British India under the reconstruction committee of the council, the New York Times reported August 28. The plan would provide at least one doctor for each thousand of the population, compared with the present ratio of about one doctor to 10,000. The scheme is to be developed and expanded every five years and the work completed in six stages, it was stated. Existing medical institutions would have to be enlarged and new ones established and a public health directorate with a network of provincial auxiliaries would be needed, it was said.

Whole Stomach Extract in the Treatment of Infantile Pellagra

From the Non-European Hospital at Johannesburg, T. Gillman and others report remarkable results in the treatment of infantile pellagra (*Nature*, August 12, p. 210). During the last three years nearly 300 children suffering from acute malnutrition have been admitted. More than 60 per cent of these manifested signs of infantile pellagra. The dominating features were edema of the limbs and, in severe cases, of the face, eyelids and genitals. The edema was associated with pellagrous skin lesions on the legs, buttocks, back, arms and face, gray hair or alopecia and patchy or diffuse dermal pigmentation. The stools as a rule were bulky, pale and foul smelling and contained much unsplit fat. The serum proteins were extremely low and there was a mild microcytic anemia. The liver was extremely fatty.

The unresponsiveness of this condition to vitamin therapy, including nicotinic acid, and a death rate of 90 per cent have been recorded by Trowell. It was therefore necessary to seek some other treatment. By improved liver biopsy Gillman and his group established that the microscopic appearances of the liver is a valuable method of assessing the severity of the condition. They studied 20 children by this method and treated them in three ways. They treated 7 with thiamine hydrochloride, nicotinic acid or brewers' yeast. Only 1 survived. Another 7 were given liver extract intramuscularly. Five survived and recovery was slow. Six were treated with 10 Gm. of desiccated hog's stomach and 10 cc. of tenth normal hydrochloric acid daily for five days. The response was dramatic: all survived. The loss of edematous fluid was shown by a fall in weight of 1 to 1½ pounds (450 to 675 Gm.) in twenty-four hours. The clinical condition remarkably improved, and the liver became almost free from fat in two weeks.

Whole extracts of hog's stomach have been occasionally used in the treatment of pellagra in adults with good results. In 7 severe cases in adults Gillman and his collaborators found the substance much more effective and rapid in its results than nicotinic acid and other vitamins. They draw the following conclusions: 1. Stomach extract is life saving in severe infantile pellagra. 2. It can be regarded as a lipotrope in view of its rapidity in depleting fat from the liver. 3. As both adults and infants respond to a single form of therapy there is no justification for regarding infantile and adult pellagra as different diseases.

Tuberculosis in Nurses

A survey of tuberculosis in nurses, organized by the Royal College of Physicians under the terms of a special bequest, has been carried out by Dr. Marc Daniels. It is the only survey of the sort in this country large enough to produce data of statistical value. The number of nursing entrants in the survey up to March 1943 was 3,764. Shortly after entry to the preliminary training school they were given Mantoux tests and x-ray examination. In the tests, 50.3 per cent were positive to old tuberculin 1 in 10,000 or 100,000, 30.5 per cent were positive only to 1 in 100 or 1,000 and 19.2 were negative. A change from negative to positive reaction (Mantoux conversion) in the first year took place in 58.4 and 78.3 per cent of two hospital groups respectively. Most of these nurses had no notable symptoms between the last negative and the first

positive test. A study was made of the tuberculosis morbidity in nurses with a clear x-ray film on entry, disclosing that 33 cases occurred in 452 nurses initially Mantoux negative and 43 cases in 2,120 initially Mantoux positive. The annual case rate was 7.4 per thousand in nurses who were Mantoux positive on entry and 18.8 in those who were Mantoux negative.

The important fact emerges that tuberculous morbidity was two and one-half times higher in nurses who were Mantoux negative on entry than in those who were Mantoux positive. The explanation is that those who are Mantoux positive on entry are a selected population in whom primary infection has produced no perceptible lesion or who have recovered from a lesion. Therefore the percentage succumbing to infection will be lower in this group than in the Mantoux negative nurses, who are an unselected group. Special care must be taken of the young nurse who is Mantoux negative on entry. She should not be required to work in a ward set aside in a general hospital for tuberculous cases. X-ray examinations and tuberculin tests should be repeated at frequent intervals and particular care given if the test is found to be changing from negative to positive.

Color Film Record of Tongue Movements. in Speech

A color film record of the tongue movements in speech, the first ever made, is described in *Endeavor*, the quarterly review of scientific progress published by Imperial Chemical Industries. The authors are a physiologist, Mr. J. Yule Bogue and Mr. Dennis Fry, who since 1939 has been occupied in research for the Royal Air Force into problems connected with the transmission and reception of speech signals. To make the film a man aged 72, whose tongue was exposed to view as the result of an operation involving removal of the right cheek, was used. A film record of the tongue movements was taken at the normal rate of twenty-four frames a second. A simultaneous record was made of the subject's speech. Thus it is possible to compare the pictures with the sounds corresponding to the tongue movements. The film sound track supplies a rough indication of the wave form of the sound that is being produced. In addition to these records made at normal speed, photographs were taken at high speed for frame by frame analysis in conjunction with cathode ray oscillograms of the speech taken at the time. The film is not only of scientific interest but also of assistance in speech therapy. It has been welcomed by the Air Force as a contribution toward the rehabilitation of flying men with facial injuries who have to be taught to speak again.

Vital Statistics

The remarkable fact that our vital statistics have improved during the war has been reported in previous letters to *THE JOURNAL*. The latest official figures for the quarter ended March 31 have just been published. They show a birth rate of 17.9 per thousand of population, which is the highest rate for the first quarter of the year since 1926. Thus there is some reversal of the declining birth rate, which was not sufficient for the maintenance of our population. Births exceed deaths by 37,941. The provisional infant mortality rate was 58 per thousand live births. This was 14 below the average for the preceding ten first quarters and the lowest on record. Marriages for the quarter numbered 62,599, lower by 12,972 than the average for the five years prior to 1943 but 8,338 higher than the corresponding first quarter average for the five years immediately preceding the war. The greatly increased marriage rate produced by the outbreak of war—which not only removed unemployment but gave family allowances to members of the fighting forces—could not be expected to continue at the same level.

PALESTINE

(From a Regular Correspondent)

JERUSALEM, Aug. 1, 1944.

Statistics on Physicians in Palestine

Second in a series of publications issued by the Central Bureau of Medical Statistics is a report of investigations carried on by Prof. R. Bacchi, in cooperation with Dr. Serolovitz, of Palestinean economic conditions with reference to physicians, both now and in the future, when the end of the war will create an entirely unprecedented situation. Intervoven with the problems of immigration and demobilization of physicians is the question of the necessity of establishing a faculty of medicine as part of the Hebrew University in Jerusalem.

The introductory chapter of the study deals with the peculiar structure of the medical profession in Palestine since 1921. At that time there were 129 Jewish physicians, or 23.6 per 10,000 Jewish inhabitants. At the same time non-Jewish physicians numbered 120, or 2.47 per 10,000 non-Jewish inhabitants. The further development may be seen in the accompanying table giving the percentages of Jewish and non-Jewish physicians in relation to the corresponding number of inhabitants. According to government statistics, the total number of physicians practicing in Palestine in 1941 was 2,244.

Physicians per 10,000 Inhabitants

	1922-24	1931-33	1934-36	1937-39	1940-42
Jews	23.6	21.9	45.1	44.1	45.9
Non-Jews....	2.47	2.18	2.25	2.44	

An analysis of the figures shows that in the non-Jewish population of Palestine the percentage of physicians has remained the same during the past twenty years (and is, moreover, one of the lowest in the world: United States [1942] 13.3, England [1932] 9.4, Switzerland [1938] 8.2, Finland [1936] 6.2).

For the Jewish population, the number of physicians in relation to the number of inhabitants was, even in 1921, double that of the international average, while by 1941 it had grown to twice as much. There is no doubt that the Jewish population of Palestine has an excess of physicians.

But what will happen if for any reason no influx of new physicians from abroad takes place and training facilities for physicians are not provided for in this country? For the coming ten or twenty years the present number of physicians will suffice for a population of three quarters of a million. After about twenty years a crisis may develop, and in 1972 practically all physicians will have disappeared. Such an event can naturally be forestalled by establishing a faculty of medicine at the Jerusalem University. An additional thirty-five physicians every year will suffice to meet the demand of the present Jewish inhabitants. The first group of fully trained physicians can be expected by the year 1953 if training is started in the near future.

Remittent Rural Fever (Febris Remittens Agriolarum)

According to data presented by Dr. J. Yatomi in 1940, 245 inmates of the Mikveh Israel Agricultural School (218 students and 36 teachers) contracted an infectious disease of an outspokenly remittent character. The maximum temperature, 104 F., was recorded in the afternoon, this rise being accompanied by rigor, which subsided as soon as sweating set in. Occasionally elevation of temperature occurred during the night too. During the day the temperature was normal but the patients complained of violent headache, particularly supra-orbitally, and of pain in the muscles. Immediately after the temperature had reached its maximum the patients felt exceptionally well and ate with good appetite. This intermittent fever

lasted from four to twelve days. The pulse rate inclined toward bradycardia. Even during the first few days the spleen was palpable, while the liver could be felt only occasionally. The blood was characterized by leukopenia, with relative increase in monocytes. Epidemiologically the following facts could be established: Contact or food infection could be ruled out. Sixty-two per cent of the students were recent immigrants to the country, while the majority of the remaining 38 per cent came from towns. Only a small number of children from rural areas contracted the infection, while agricultural workers from Turkey, Persia and Mesopotamia who were employed at the settlement were spared altogether. It seems probable, therefore, that immunity after earlier infection must be taken into consideration. There was no indication of transmission by insects. The probable carrier of the infection is a special type of micro-tus, since prior to and during the epidemic a great number of these field mice were found. It is assumed that the germ was present in the fields and in the harvest and reached susceptible persons through the skin.

Venereal Diseases Among the Jewish Population of Palestine

In an article by Dr. A. Dostrovsky and Dr. F. Sagher, the incidence of venereal diseases among the Jewish population of Palestine is discussed. The data published by the authors refer to inpatients as well as outpatients of the Hadassah University Hospital in Jerusalem, and it is pointed out that caution should be exercised in applying them to the country as a whole. Among the 116,276 patients registered at the dermatologic outpatient department during the years 1920-1942, there were 986 venereal cases, or an incidence of 0.85 per cent. Six hundred and twenty of the patients were suffering from syphilis, 355 from gonorrhea and 11 from ulcus molle. In Jews of Oriental origin venereal diseases were twice as frequent as in Ashkenazim. The highest figures recorded were those for the years immediately following the first world war (1920, 2.7 per cent; 1922, 1.7 per cent). In 1942 the figure dropped to 0.2 per cent. The war years 1939-1942 have "so far shown no increase, although a similar postwar peak should be expected this time too."

Although the study has the shortcomings of all venereal disease statistics, it has, on the other hand, the advantage of covering a period of twenty-two years, so that there is some justification in applying the result to the Jewish sector as a whole. It may be concluded that the incidence of venereal diseases among the Jews of Palestine is actually very low.

Marriages

- ROBERT FREDERICK LAMAR, Kansas City, Mo., to Miss Hazel M. Swanson of New Bedford, Mass., in Brisbane, Australia, March 21.
- WILLIAM CASPER KITE JR., Oklahoma City, to Miss Dorothy Ann Havener of Middletown, N. Y., September 2.
- DALE BRYAN PARSHALL, South Bend, Ind., to Miss Margaret Grace McDaniel in Pickens, S. C., August 5.
- MARGUERITE PATRICIA MCCARTHY, Syracuse, N. Y., to Mr. Bertram James Brough of New York, July 11.
- LEOPOLD A. SCHNEIDER, Ninety Six, S. C., to Miss Inez Jennings Holloway of Chappells, August 16.
- LATHA MITCHELL DONALSON, Fayetteville, Tenn., to Miss Claudie May Taylor in Franklin, August 1.
- ELLET HALLER DRAKE, Mobile, Ala., to Miss Frances Margaret Moyer at Spring Hill, August 15.
- WILLIAM CHARLES GAUNTT, Rochester, Texas, to Miss Eugenia Tate of Kountze in July.
- ROY YOUNG, Port Arthur, Texas, to Miss Evelyn Craven of Chattanooga, Tenn., May 1.

Deaths

Joelle Cornelius Hiebert @ Lewiston, Maine; Boston University School of Medicine, 1923; clinical instructor of obstetrics at his alma mater from 1924 to 1931 and instructor of preventive medicine and first aid, Gordon Theological College, from 1929 to 1931; director of the Androscoggin County Tuberculosis Association; member of the American College of Hospital Administrators, American Hospital Association, American Protestant Hospital Association and the American Society for the Control of Cancer; a trustee and president in 1941-1942 of the New England Hospital Assembly; member and past president of the Maine Hospital Association; a member of the Boston Hospital Superintendents Club and the Maine Civilian Defense Committee; member of the advisory council of the Maine State Department of Health and Welfare; trustee of Oak Grove School, Vassalboro; on the editorial board of the *Journal of the Maine Medical Association*; resident physician and superintendent of the Medical Mission Dispensary from 1924 to 1931; since 1931 medical superintendent of the Central Maine General Hospital, where he died June 8, aged 51.

James Henry Taylor, Indianapolis; Indiana Medical College, Indianapolis, 1878; member of the Indiana State Medical Association; professor emeritus of pediatrics at the Indiana University School of Medicine; past president of the Indianapolis Medical Society; president of the board of trade of Indianapolis, 1915-1916; served as president of the Summer Mission for Sick Children and as a member of the Family Welfare Board; formerly a member of the board of aldermen; for many years visiting physician at the Indianapolis Orphans' Home; one of the founders and for many years president of the Arsenal Building and Loan Association; died July 23, aged 81.

David Powrie Maitland, Jackson, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; member of the Minnesota State Medical Association; past president of the Jackson County Medical Society; for over twenty years chairman of the board of health of Jackson; served as coroner of Jackson County; during World War I had been examining physician and a member of the Jackson County Draft Board; for many years also served on the United States Pension Board; examining physician for the local Selective Service Board during World War II; died June 25, aged 77, of coronary heart disease.

Alexander Alexion, New York; National University of Athens School of Medicine, Greece, 1897; died July 30, aged 71, of cerebral hemorrhage.

Oscar Henning Anderson @ Plum City, Wis.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; owner of the Plum City Hospital; died in St. Luke's Hospital, St. Paul, Minn., June 20, aged 60, of congestive heart disease with edema, hypertensive heart disease and pulmonary embolism.

James Eddy Arnold, Minneapolis; Rush Medical College, Chicago, 1917; formerly village health officer and school physician for Mountain Iron, Minn.; on the staff of the Minneapolis General Hospital, where he died July 17, aged 54, of coronary sclerosis and diabetes mellitus.

Frederick William Becker, Newark, N. J.; College of Physicians and Surgeons, New York, 1888; also a pharmacist; member of the Medical Society of New Jersey; formerly member of the city board of health; served on the staff of the Newark City Almshouse, Maplewood; died in the Presbyterian Hospital July 11, aged 83, of uremia and hypertrophy of the prostate.

Glenn A. Brandt, Palo, Iowa; Keokuk Medical College, College of Physicians and Surgeons, Keokuk, 1901; member of the Iowa State Medical Society; died in Shellsburg June 8, aged 71, of injuries received when the automobile in which he was driving was struck by a train.

Michael Joseph Buck, Wilkinsburg, Pa.; Jefferson Medical College of Philadelphia, 1872; Hahnemann Medical College of Philadelphia, 1876; died in the Western Pennsylvania Hospital, Pittsburgh, June 14, aged 92.

Judson Charles Cole, Emmett, Kan. (licensed in Kansas in 1901); at one time coroner of Atchison County; formerly on the staff of the Atchison, Topcka and Santa Fe Railway Hospital, Topcka; died June 25, aged 84, of uremia.

Edna Bowden Dayton, Remsenburg, N. Y.; Woman's Medical College of Pennsylvania, Philadelphia, 1913; died July 11, aged 66, of sinus heart block.

Charles A. Dimond, Keokuk, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1903; member of the Iowa State Medical Society; served as a member of the city council and for many years city physician; died June 11, aged 73, of chronic endocarditis.

William H. Douglass, Benton City, Mo.; Barnes Medical College, St. Louis, 1898; honorary member of the Missouri State Medical Association; died in Mexico May 1, aged 69, of arthritis.

Bishop L. Elam, Centralia, Okla. (licensed in Oklahoma under the act of 1908); served as mayor of Centralia; died May 8, aged 71.

Sidney A. Faulkner, Whitney, Texas; Louisville (Ky.) Medical College, 1890; died June 8, aged 77, of heart disease.

James Murray Fettes, Spencer, Iowa; Trinity Medical College, Toronto, Ont., Canada, 1904; died June 6, aged 64.

Arthur John Fletcher @ Danville, Ill.; Northwestern University Medical School, Chicago, 1909; member of the American Academy of Pediatrics; president of the Vermilion County Medical Society; veteran of the Spanish-American War and World War I; on the staffs of the Lake View Hospital and St. Elizabeth Hospital, where he died July 24, aged 65, of heart disease.

Archibald Whittington George @ Detroit; Baltimore Medical College, 1911; a charter member and formerly a director of the American Association of Industrial Physicians and Surgeons; chief surgeon of the Packard Motor Car Company for many years; on the staff of the Harper Hospital, where he died July 21, aged 60, of sarcoma of the left ureter.

Robert Marion Golson, Prattville, Ala.; University of Tennessee Medical Department, Nashville, 1891; member of the Medical Association of the State of Alabama; died July 15, aged 78, of arteriolar sclerosis.

Morton Guzy @ Bridgeton, N. J.; Medical College of Virginia, Richmond, 1939; served an internship at the Jewish Hospital in Philadelphia; secretary of the Bridgeton Hospital staff; died July 20, aged 29, of coronary thrombosis and diabetes mellitus.

Sherwood Ackler Haggerty, Richfield Springs, N. Y.; Albany Medical College, 1895; died June 15, aged 73, of lymphosarcoma.

John Arthur Lamb, Kalispell, Mont.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1898; member of the Montana State Medical Association; served during World War I; captain, medical reserve corps, U. S. Army, not on active duty; on the staff of the Flathead County Hospital; on the courtesy staff of the Kalispell General Hospital; city health officer and local registrar; died June 20, aged 70, of carcinoma of the liver and pancreas.

Morris Hallowell Layton Jr. @ Harrisburg, Pa.; Medico-Chirurgical College of Philadelphia, 1910; died in the Harrisburg Hospital June 4, aged 56, of cerebral hemorrhage.

Daniel Guy Leach, Tucson, Ariz.; Central College of Physicians and Surgeons, Indianapolis, 1901; died June 24, aged 65.

Joseph Levy, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1902; member of the Louisiana State Medical Society; for many years on the staff of the Charity Hospital; died July 8, aged 64.

Charles Patterson Marsh, Petersburg, Tenn.; University of Nashville Medical Department, 1909; served in France during World War I; died July 5, aged 61.

Jessie Laird Robb Marshall, New York; University of Birmingham Faculty of Medicine, England, 1924; physician at Teachers College of Columbia University and the Horace Mann-Lincoln School; lecturer on child health at Columbia University; died in St. Luke's Hospital July 19, aged 45, of peritonitis caused by a carcinomatous growth.

Flora Eva Frost Moody @ Springfield, Mass.; Tufts College Medical School, Boston, 1898; died June 26, aged 73, of cerebral hemorrhage, hypertension and osteoarthritis.

Julius Daniel Mueller, Flandreau, S. D.; Creighton University School of Medicine, Omaha, 1931; served an internship at the Dr. W. H. Groves Latter-Day Saints Hospital, Salt Lake City, Utah; on the staff of the Flandreau Municipal Hospital; coroner for Moody County; died June 29, aged 39, of injuries received when crushed by a truck.

Emil Alfred Muller, Glen Cove, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1898; died June 13, aged 67, of arteriosclerosis, hypertension and acute cardiac failure.

James Moffett Norris, Northampton, Mass.; Western Reserve University School of Medicine, Cleveland, 1935; served an internship at the Charity Hospital in Cleveland and the LaFayette Home Hospital in LaFayette, Ind.; captain in the medical reserve corps, U. S. Army; served on the staffs of Veterans Administration facilities in Lyons, N. J., Sunmount, N. Y., and Northampton; died July 15, aged 39.

Lovett E. Park, Columbus, Ohio; Eclectic Medical Institute, Cincinnati, 1889; formerly on the staff of the Institution for Feeble-minded; died July 12, aged 81.

Robert Alex T. Patterson, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1900; died in the Philadelphia General Hospital in July, aged 67, of carcinoma of the lung.

Marcellus Leroy Peterson, Cincinnati; Eclectic Medical Institute, Cincinnati, 1899; served during World War I; lieutenant colonel in the medical reserve corps of the U. S. Army from Feb. 21, 1941 to Nov. 27, 1943, when he was relieved from active duty because of age; died in the Bethesda Hospital June 15, aged 66, of ruptured myocardial infarct with intrapericardial hemorrhage.

Alfred Noroton Phillips, Glenbrook, Conn.; College of Physicians and Surgeons, New York, 1883; member of the Connecticut State Medical Society; formerly an executive of the Phillips Chemical Company; a director of the Stamford Hospital, Stamford; died August 1, aged 88.

Leo Francis Pierotti, Memphis, Tenn.; St. Louis University School of Medicine, 1931; member of the Tennessee State Medical Association; served an internship and a residency in surgery at St. Mary's Group of Hospitals in St. Louis; formerly an intern, secretary and member of the staff at St. Joseph's Hospital, where he died July 15, aged 37, of coronary occlusion.

William Henry Pipes, Jackson, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1906; member of the Louisiana State Medical Society; died July 8, aged 66.

John Rogers Pollock @ Ardmore, Okla.; Chicago College of Medicine and Surgery, 1909; died June 28, aged 61.

Herbert Ellis Rodley, Chico, Calif.; College of Physicians and Surgeons of San Francisco, 1910; died in the Enloe Hospital July 5, aged 60, of cardiac decompensation.

Clement E. V. Sams, Haven, Kan.; American Medical College, St. Louis, 1894; died in June, aged 75, of coronary occlusion.

Richard Savine, Long Island City, N. Y.; Long Island College Hospital, Brooklyn, 1907; member of the Medical Society of the State of New York; died July 19, aged 67, of cerebral hemorrhage.

Bert D. Shedd, Arcade, N. Y.; Cleveland Homeopathic Medical College, 1898; member of the Medical Society of the State of New York; formerly mayor, school physician, county coroner and health officer; died July 18, aged 72, of coronary embolism.

Joseph Leslie Sherrick @ Monmouth, Ill.; Johns Hopkins University School of Medicine, Baltimore, 1914; fellow of the American College of Physicians; served an internship at the Massachusetts General Hospital, Boston, 1914-1915; on the staff of the Monmouth Hospital; trustee, Monmouth College; director of the Second National Bank and associate medical director of the Illinois Bankers Life Assurance Company; died July 28, aged 56, of heart disease.

Arthur Montell Smith @ Piedmont, Calif.; Cooper Medical College, San Francisco, 1899; an Affiliate Fellow of the American Medical Association; fellow of the American College of Physicians; formerly a member of the state board of medical examiners; during World War I served overseas as a captain in the medical corps of the U. S. Army; served as chief of medical service, Samuel Merritt Hospital, Oakland, where he died July 21, aged 72, of heart disease.

Rose Marie Vastola Smith, Rome, N. Y.; University of Buffalo School of Medicine, 1924; served an internship at Buffalo City Hospital, Buffalo; formerly connected with the New York City health department; died in the Station Hospital, Rome Army Air Field, July 6, aged 48, of carcinoma.

William Adelbert Smith, Petersburg, Mich.; Cleveland Homeopathic Medical College, 1903; for many years member and president of the school board; served as village president and as village and township health officer; on the staffs of the Toledo Hospital, Toledo, Ohio, and the Mercy Hospital, Monroe; president of the H. C. McLachlin & Company State Bank; died July 9, aged 67.

Ulysses G. Spohn, Fairgrove, Mich.; Detroit College of Medicine, 1906; member of the Michigan State Medical Society; served on the staff of the Samaritan Hospital, Bay City; died in East Tawas July 22, aged 73, of coronary thrombosis.

Andrew Wilton Springs, Colp, Ill.; National Medical University, Chicago, 1905; formerly physician in charge of the Madison Coal Corporation Hospital in Dewmaine; died July 22, aged 75, of heart disease.

Harry Erskine Tatum, Brunswick, Mo.; Jefferson Medical College of Philadelphia, 1900; member of the Missouri State Medical Association; served as president of the Charleston County Medical Society; county coroner; for many years a member of the school board; died July 1, aged 67, of coronary embolism.

William J. Thompkins, Washington, D. C.; Howard University College of Medicine, Washington, 1905; formerly assistant health commissioner, department of hygiene and communicable diseases, Missouri State Board of Health; served as curator of the Lincoln University, Jefferson City; formerly superintendent of the Kansas City General hospital number 2, Kansas City, Mo.; recorder of deeds for the District of Columbia; died August 4, aged 66.

George Monroe Tolhurst, Atlanta, Ga.; International Medical Missionary College and Training School for Nurses, Atlanta, 1908; died in the Grady Hospital June 27, aged 68, of hypertensive cardiovascular disease.

Frank F. Tourner, Bloomington, Ind.; Kentucky University Medical Department, Louisville, 1899; member of the Indiana State Medical Association; died July 6, aged 85, of hypostatic pneumonia.

James Walter Van Blaricum @ Minneola, Kan.; Kansas City (Mo.) Medical College, 1901; for many years member of the school board; died June 4, aged 70, of bronchial asthma.

Fred Ellridge Varney, North Chelmsford, Mass.; Medical School of Maine, Portland, 1886; member of the Massachusetts Medical Society; past president of the Middlesex North District Medical Society; school physician for many years; on the staff of the Lowell General Hospital, Lowell; died June 8, aged 83, of coronary heart disease.

Robert Lee Walker, Crabtree, N. C.; Kentucky School of Medicine, Louisville, 1889; died in the Haywood County Hospital, Waynesville, June 28, aged 80.

James D. Woodley, Indianapolis; Baltimore University School of Medicine, 1891; died May 23, aged 76, of heart disease.

KILLED IN ACTION

Peter Leo Demeter, Webster, Mass.; Middlesex University School of Medicine, Waltham, 1938; served an internship at the Buffalo Columbus Hospital, Buffalo; commissioned a first lieutenant in the medical corps, Army of the United States, on Nov. 4, 1942; later promoted to captain; went overseas in 1943; took part in the North African campaign and the invasion of Sicily; killed in action in Italy, July 26, aged 30.

CAPT. PETER L. DEMETER
M. C., A. U. S., 1914-1944

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

This report is based on studies by the Council and returns on questionnaires sent to medical officers by the Committee on Postwar Medical Service and analyzed by Lieut. Col. Harold C. Lueth, M. C., Surgeon General's Liaison Officer.

POSTWAR PLANNING

EDUCATIONAL FACILITIES REQUIRED FOR RETURNING MEDICAL OFFICERS

VICTOR JOHNSON, M.D., PH.D.

AND

F. H. ARESTAD, M.D.

Secretary and Assistant Secretary, Respectively, Council on Medical Education and Hospitals

CHICAGO

In November 1942 the Council on Medical Education and Hospitals took cognizance of the fact that medical educational facilities at the graduate and postgraduate levels would be severely taxed in the postwar period because many medical graduates were and would be entering military service with a minimum of training beyond the internship and would desire additional education after the war. At that time the Council embarked on a study of the required facilities to meet this future need. This project was reported to the House of Delegates in April 1943.¹

In its first preliminary report on this study the Council estimated that "... with a normal civilian complement of 5,500 residents the approved hospitals may be called on to furnish a total of 12,000 or 13,000 residencies in the immediate postwar period."² The Council further concluded from its preliminary survey that "... it should be possible to develop the required twelve or thirteen thousand residencies."

In its report to the House of Delegates in April 1944, the Council stated³ that "In the Council's planning for these postwar services it became clear early that we were working entirely on the probable available supply of educational opportunities. The question of demand for them was entirely unknown and will depend (in part) on what the men now in service will desire after the war."

THE SURVEY OF MEDICAL OFFICERS

This very problem was then being attacked by the Committee on Postwar Medical Service. This committee was established by the American Medical Association in collaboration with the American College of Physicians and the American College of Surgeons and also includes representatives of the Association of American Medical Colleges, the American Hospital Association, the Catholic Hospital Association, the Federation of State Medical Boards of the United States, the Procurement and Assignment Service, the Advisory Board for Medical Specialties and the Veterans Administration. A major project of this committee has been a study of the postwar educational desires of medical officers, being conducted with the cooperation of the Surgeons General of the Army, the Navy and the Public Health Service. A questionnaire on this (and other important) questions was devised and has now been mailed to every medical officer in the services. A pilot questionnaire was first sent to 3,000 officers selected at random, representing all age

groups, all services and all theaters of operation. Analyses of the early returns⁴ and a more detailed presentation of the educational plans of the first thousand of the officers replying⁵ have been made by Lieut. Col. Harold C. Lueth.

The latter of these two reports, which appeared in the Forty-Fourth Annual Educational Number of THE JOURNAL by courtesy of the Committee on Postwar Medical Service, provides figures permitting preliminary estimates of the total postwar educational requirements of medical officers and civilian graduates. From these requirements must be subtracted the currently available facilities to indicate what further educational opportunities must be developed to meet the demand.

POSTWAR EDUCATIONAL DESIRES OF MEDICAL OFFICERS

The data in tables 1, 2, 3 and 6 are recapitulations of Lueth's figures.⁵ Table 1 shows the distribution of officers replying according to year of graduation and the

TABLE 1.—Postwar Educational Desires of the First 1,000 Medical Officers Replying to a Questionnaire Sent to 3,000 Medical Officers Selected at Random and Representing All Theaters of Operation and the United States

Group Number	Dates of Graduation	Desire No Educational Training	Desire 6 Months or Less or Unspecified Period	Desire More Than 6 Months Training	Total Replies by Groups
1.....	1941-1943	4	41	119	164
2.....	1938-1940	21	28	148	207
3.....	1935-1937	30	82	69	100
4.....	1930-1934	63	79	50	222
5.....	1920-1929	60	82	38	180
6.....	Before 1920	17	16	4	37
Totals.....		204	338	458	1,000

Note: Since there were 1,000 replies, any figure can be converted to per cent of the officers replying by pointing off one decimal place; 164 becomes 16.4 per cent.

postwar educational desires. No further formal education was planned by 20.4 per cent of all officers replying. Some full time training was requested by 79.6 per cent. Of these 33.8 per cent desired six months or less training, which was classified as review or refresher courses, and 45.8 per cent desired more than six months' training in hospital house officerships. Excluding group 6 (the oldest officers) from whom the fewest replies were received, the replies indicate that with increasing age, on the one hand, there is an increasing tendency to anticipate either no future training or, at most, review and refresher courses when further education is desired. On the other hand, the younger graduates provide most of the requests for hospital training; nearly 60 per cent of such requests came from men who graduated in 1938 or later. These general trends might have been anticipated in advance, but the large totals are surprising, as is also the fact that nearly two thirds of those who graduated before 1930 also desire some further training.

1. J. A. M. A. 121: 1397 (April 24) 1943.

2. J. A. M. A. 124: 40 (Jan. 1) 1944. Compare with estimates in the present report, page 255.

3. J. A. M. A. 124: 1302 (April 29) 1944.

4. J. A. M. A. 125: 558 (June 24) 1944.

5. J. A. M. A. 125: 1099 (Aug. 19) 1944.

DURATION OF TRAINING DESIRED

Table 2 shows the number of courses of varying durations requested by the thousand men who replied. Some officers requested more than one course, since 796 men requested 970 courses. Such instances were more frequent in the shorter courses (average 1.34 courses per officer) than in the longer house officerships (average 1.13 requests per officer).

There was a relatively small number of specific requests for courses of two months or less. Over 60 per cent of the 452 requests for the shorter courses specified three to six months. Of the 518 requests for house officerships, 47 per cent were for nine months or a year, 32 per cent for two years and 21 per cent for three years or more. Almost all of those desiring three years graduated in 1938 or later. The average duration of the 518 house officerships requested was 1.73 years.

TABLE 2.—Number of Courses of Different Durations Requested by 796 of the 1,000 Officers in Groups 1 to 6 Replying to the Questionnaire

Groups	Short Courses Review or Refresher 6 Months or Less						Long Courses Internships, Residencies or Fellowships, More Than 6 Months					Grand Total, Short and Long Courses
	1 Mo.	2 Mo.	3 Mo.	6 Mo.	Duration Not Given	Total	9 Mo.	1 Yr.	2 Yrs.	3 or More Years	Total	
Group 1 (1941-1943).....	0	0	6	23	26	55	0	29	55	57	141	195
Group 2 (1938-1940).....	0	4	18	21	16	59	5	67	56	39	167	226
Group 3 (1935-1937).....	12	7	26	52	19	116	4	36	24	8	72	188
Group 4 (1930-1934).....	11	8	23	46	17	110	17	45	23	5	93	203
Group 5 (1920-1929).....	9	5	27	31	21	93	9	23	6	1	41	134
Group 6 (Before 1920).....	1	0	3	5	10	19	0	4	0	0	4	23
Totals.....	33	24	108	178	109	452	35	209	164	110	518	970

Note: Since nearly 1,000 courses were requested, any figure can be converted into percentage of the courses requested by pointing off one decimal place: 19.6 becomes approximately 19.6 per cent. Note that one man may want 2 or more courses, since 796 men requested 970 courses.

INTERNSHIPS AND RESIDENCIES

Table 3 deals with requests for hospital house officerships of nine or more months' duration, classified according to the subject or field of medicine desired.

TABLE 3.—Requests for Postwar House Officer Training of More Than Six Months' Duration from 458 Medical Officers of the 1,000 Who Replied

Field in Which Training is Desired	Group 1	Group 2	Group 3	Group 4	Group 5	Group 6	Total Groups 1 to 6 by Sub- jects
Anesthesiology.....	1	3	2	6
Dermatology and Syphilology.....	1	1	..	1	1	..	4
.....	23	31	11	9	8	..	87
.....	11	12	9	11	7	1	51
.....	3	..	1	4
.....	20	27	5	7	3	..	62
Ophthalmology.....	1	3	6	14	1	..	25
Orthopedic Surgery.....	5	6	3	2	1	..	17
Otolaryngology.....	3	4	4	13	3	..	27
Pathology.....	3	5	2	..	1	1	11
Pediatrics.....	5	9	1	1	2	..	18
.....	1	1
.....	4	6	3	4	3	..	20
.....	..	1	1	..	1	..	3
Radiology.....	1	4	4	3	1	..	13
Surgery.....	52	53	17	21	7	2	154
Urology.....	4	2	3	3	1	..	13
Total courses by age groups.....	141	167	72	93	41	4	518

Note: Since nearly 1,000 (actually 970) courses were requested in this category and that of table 6, any figure can be converted into percentage of all courses desired by pointing off one decimal place: 51.8 becomes approximately 51.8 per cent.

Nearly 70 per cent of the 518 requests for internships and residencies were in the following four fields: surgery (30 per cent), internal medicine (17 per cent), obstetrics and gynecology (12 per cent) and general training, such as a mixed residency or "second year internship" (10 per cent). Less than 5.2 per cent

of the internship and residency requests were for training in each of the remaining fields, and there were less than 1 per cent of the requests for work in each of the following subjects: neurosurgery, dermatology and syphilology, public health, hospital administration and plastic surgery.

ESTIMATED REQUIRED EXPANSION OF HOUSE OFFICERSHIPS

An attempt is made in table 4 to arrive at a tentative estimate of the additional hospital educational facilities which will be required in all fields after the war by all officers seeking more than six months' training. Any such estimates are necessarily hazardous in the extreme, because of several unknown variables which might greatly modify the resulting figures. However, it is essential that an approximation be made at once to facilitate definitive planning.

In table 4, column A, is shown the total number of physicians certified by the American boards in the specialties to 1944. Column B is taken from the figures provided by Lueth's study.⁵ Column C gives provisional estimates of the probable total number of all medical officers in the armed forces who will want more than six months' training. The figures in this column are twenty times the numbers of requests from the first thousand replies (column B) received from the 3,000 officers to whom the pilot questionnaires were sent. This estimate assumes (a) that there are 54,000 medical officers in the services, (b) that there was a fair sampling of the officers receiving the pilot questionnaire, (c) that about one fourth of those requesting training of this kind may be unable to carry out their plans, and (d) that nearly 10 per cent of the 2,000 medical officers to whom pilot questionnaires were mailed, but from whom replies had not been received at the time of tabulation, will take further training similar to that of the officers who replied. The last of these assumptions is probably the most seriously open to question and may later require considerable modification in the light of further returns on the questionnaires of the Committee on Postwar Medical Service. These are now being received at a rapid rate. All information received is being transferred at once to International Business Machine punch cards to facilitate further analysis.

It is of interest to compare the figures of column C with those of column A. An estimated 10,260 officers will seek more than six months of specialty training (but not necessarily certification) after the war. This is nearly one-half the total number of specialists (23,465) now certified by the American boards.

In column D are given the numbers of assistant residents, residents and fellows in the normal prewar year 1941. To obtain the total number of house officerships required, these prewar figures must be added to the estimated numbers of returning medical officers desiring training. This total is given in column E.

The house officer facilities available in 1943 are shown in column F. These currently existing places must be deducted from the total places required (column E) to arrive at a provisional estimate of additional facilities which must be developed, given in column G. Provided the basic assumptions made are reasonably accurate, it appears that nearly 10,000 additional* residencies will be required for returning officers, should demobilization be rather rapid.

ures of column G should be adjusted to the assumption currently in vogue that demobilization will extend over some time.

If we assume that about one half of the medical officers will be discharged and will embark on their postwar educational plans during the first year after the war, a total of approximately 4,590 additional residencies (column H) will be required in addition to the 5,796 now available. Should medical officers in all categories be discharged in equal numbers every three months throughout a two year demobilization period, the numbers seeking hospital positions will be relatively small at first but will mount steadily for two years. Under these conditions the maximum figure will be reached toward the end of the second

TABLE 4.—*Additional Postwar House Officerships Required: Tentative Estimates*

Totals.....	23,465	513	10,260	5,256	15,516	5,796	9,720	4,590

Note.—Column B includes the courses requested by officers in all age groups (see table 3, last column). The total (513) is 5 less than total in tables 2 and 3 because Hospital Administration (2 requests) and Public Health (3 requests) were omitted. There are no specialty boards or approved residencies in these fields. Column C contains a tentative estimate for the desires of 54,000 medical officers. See discussion on page 254 for method of computation and variables which would modify the estimates. Column H is the estimated number in the first postwar year, if one half of the medical officers are discharged in that year ($C/2 + D - F$).

1. J. A. M. A. 122:1119 (Aug. 14) 1943.

2. This pertains to general hospital training independent of specialties in second year internships or mixed residencies; in columns D and F the figures 183 and 154 are for mixed residencies.

3. Included under Internal Medicine in table 3.

4. Includes Malignant Diseases, Thoracic Surgery, Traumatic Surgery and the subspecialty Proctology.

RATE OF DEMOBILIZATION

The Council on Medical Education and Hospitals has recognized⁵ that "the rate of demobilization of medical officers will bear significantly on our planning for their postwar training." The estimates contained in table 4 must take this into account, since the additional 9,720 residencies (total of column G) and the total of 15,516 residencies for civilians plus discharged officers (column E) would apply provided all officers desiring such training were discharged within a few months, on conclusion of the war, which is not likely to happen. While the rate of demobilization cannot now be estimated with assurance, the fig-

year of demobilization. At that time a full 75 per cent of all discharged physicians seeking house officerships will be in such positions, which may require about 7,500 residencies in addition to the 5,796 now available.⁶

RESIDENCIES REQUIRED IN SPECIFIC FIELDS OF MEDICINE

Preliminary approximations to the number of hospital positions required in the various specialties are also given in table 4, column H. If our basic assumptions have been reasonably sound, it appears that an increase

6. The total estimated in this way, about 13,300, may be compared with the Council's estimate of January 1944, when a figure of 12,000 or 13,000 was arrived at on the basis of the scanty information then available.

of about 80 per cent will be required during the first year in the total number of residencies and that the percentages of expansion of available places required in the various special fields may be about as shown in table 5. Not included in this table are the following subjects, in which relatively small numbers of officers

TABLE 5.—Percentage Increase in Numbers of Postwar Residencies Which May Be Required: Tentative Estimates

Otolaryngology.....	120%	Orthopedic surgery.....	50%
Surgery.....	100%	Pediatrics.....	50%
			40%
			35%
Urology.....	70%		30%
Internal medicine.....	50%		

evinced interest: anesthesiology, dermatology and syphilology, neurologic surgery, physical medicine and plastic surgery. While some expansion of educational opportunities will be required in these fields, replies from more officers in the services are required to justify hazarding an estimate of the required additional facilities needed.

The field of "general training" requires special mention. In table 4 it is estimated that over 1,000 officers may seek such mixed residencies or second year internships. Although approved mixed residencies in non-internship hospitals numbered only 154 in 1943, it must be remembered that all internship hospitals are also approved for mixed residencies. There are now over 700 such hospitals providing nearly 8,000 internships in peacetime. There seems to be no doubt that these institutions will be capable of providing for the additional requirements for general hospital training.

FULL TIME REVIEW AND REFRESHER COURSES

Review and refresher courses were requested by 338 officers (table 1). The total number requested was 452 courses (table 2), varying in duration from one

TABLE 6.—Requests for Postwar Review or Refresher Courses of Six Months' Duration or Less, from 338 Medical Officers of the 1,000 Who Replicated

Field in Which Training Is Desired	Group 1	Group 2	Group 3	Group 4	Group 5	Group 6	Total Groups 1 to 6 by Subjects

Total requests by age groups.....	55	50	116	110	93	19	452

Note: Since nearly 1,000 (actually 970) courses were requested in this category and that of table 3, any figure can be converted into percentage of all courses desired by pointing off one decimal place: 452 becomes approximately 45.2 per cent.

to six months. The fields in which such training is desired are shown in table 6. The largest number of requests were for work in the same four fields which were most popular in the case of house officerships. Over 75 per cent of the requests were for the following

subjects: general training (23 per cent), internal medicine (22 per cent), surgery (19 per cent) and obstetrics and gynecology (12 per cent). Less than 4 per cent of the requests were for work in each of the remaining fields of medicine.

Again, it is incumbent on us to try to translate the expressed desires of the first thousand officers who replied to the questionnaire sent to 3,000 physicians in the services into the probable demand from all medical officers after the war. This must be done now, even at the risk of seriously miscalculating, and an attempt at this is made in table 7. Recalculations will be made on the basis of the continuing studies of the Committee on Postwar Medical Services.

In this table are given the attendance and the number of courses at various full time postgraduate courses during the year 1943-1944, classified according to duration of training and the specialty or field of interest of the physician.

In the last column of table 7 is given the estimated total number of courses desired by medical officers in the fields indicated.⁷ Expansion of presently available facilities is needed in all of the fields indicated. The most illuminating figures are those of the last two pairs of lines across the bottom of table 7, relating to the duration of the courses available and desired. In 1943-1944 over 90 per cent of the participating physicians were in postgraduate full time courses of one month or less duration. Yet over 90 per cent of the probable demands for short term training will be for courses of about two or more months. It appears that one of the most acute needs for expansion of postwar educational opportunities will be in full time review and refresher courses of two to six months' duration.

TRAINING IN THE BASIC MEDICAL SCIENCES

In the first 1,000 questionnaires returned there was an insignificant number of specific requests for further work entirely limited to the basic medical sciences. However, it must be recognized that sound advanced training in any of the medical fields requested by medical officers must include basic science instruction and review. In planning internships and residencies for returning physicians it is essential to incorporate appropriate work in biochemistry, bacteriology, physiology, anatomy and pathology. Too often, in the typical residency of peacetime, the clinical responsibilities of the physicians allowed insufficient time for such a well rounded educational program.

HOW CAN POSTWAR EDUCATIONAL NEEDS BE MET?

Meeting the requirements of returning medical officers for additional training is a serious responsibility which will require the continued joint efforts of the Committee on Postwar Medical Service, the Council on Medical Education and Hospitals, the Surgeon General of the Army, Navy and Public Health Service, hospitals approved for internships and residencies, the American boards in the medical specialties, medical schools, state licensing boards, the Veterans Administration, foundations, county and state medical societies, and every institution capable of providing advanced training to physicians.

On these physicians rests a large share of the responsibility for the quality of medical care to be provided the nation in the decades following the war. Many entered the services after an abbreviated internship.

7. These figures are twenty times those in the last column of table 6. See page 254 for discussion of the basis for this calculation. Note that table 7 omits estimates in hospital administration, neuro-surgery and public health.

Others recognize the need for further education to equip themselves to return to their former practices or to new locations in which they desire to work.

The Council on Medical Education and Hospitals of the American Medical Association recommends the following, to meet the educational challenge of the postwar period:

1. Every hospital approved by the Council for internships should review its present and potential facilities and be prepared on request to submit to the Council estimates of the additional physicians it can accommodate as house officers in general medical training without jeopardizing high educational standards.

2. Every residency and fellowship hospital approved by the Council and acceptable to the various American

feasibility of allowing credit for such graduate externships in the training requirements for certification.⁸

6. Schools engaged in undergraduate, postgraduate and graduate education, medical societies and foundations should plan especially to meet the probable demands for full time review and refresher courses of two to six months' duration.

7. All participating hospitals and schools should incorporate into all postwar house officer training appropriate work in the basic medical sciences, which will require close cooperation between hospitals, medical societies and medical schools.

8. Consistent with the demands of national security and the postwar military needs, plans for the demobilization of medical officers should provide for teachers

Note.—Part time courses (236 in number) which were given to 2,873 physicians in the year 1943-1944 are not included.

The figures given are for numbers of physicians accommodated in short courses in the year 1943-1944 and for the numbers of courses involved.

These preliminary estimates (bottom line and last column) of total postwar short courses required for medical officers were obtained by expanding the requests from 1,000 officers twenty times, as was done in column C, table 5. See discussion of this calculation in text, page 254. The horizontal totals in the last line exceed those of the vertical totals in the last column because the latter does not include estimates of required courses in hospital administration, neurosurgery and public health.

boards should be prepared to submit to the Council and the respective boards estimates of the additional physicians it can accommodate as house officers in already approved residencies, having in mind initially the required expansion estimated in table 5, as well as the necessity for preserving a high quality of training.

3. Every internship hospital not now approved by the Council for residencies should be prepared to report on such facilities it may possess as may warrant consideration for approval of residencies, particularly in those specialties requiring most expansion.

4. Every approved residency hospital which has not yet developed its educational programs to full capacity should consider the organization of additional residencies in specialties not yet approved by the Council.

5. Hospitals approved for house officer training should consider developing graduate externships to provide training of short duration to discharged officers not housed at the hospital but engaged in full time hospital work. Specialty boards should consider the

required for the training of discharged officers to be demobilized before the prospective students.

9. Although it may be necessary to modify the estimates here published when further questionnaires have been returned from medical officers to the Committee on Postwar Medical Service, plans by all medical educational institutions for expanded postwar facilities should commence at once.

10. Full use for educational purposes should be made of the period between the surrender of Germany and that of Japan to provide training for as many officers as possible while still retained on active service.

The Committee on Postwar Medical Service and the Council on Medical Education and Hospitals are moving forward with this program to the end that a complete list of available facilities may be published as soon as possible.

8. The American Board of Psychiatry and Neurology has already considered this plan, which was first suggested to the Council by that board.

**Bureau of Legal Medicine
and Legislation****MEDICOLEGAL ABSTRACTS**

Malpractice: Statute of Limitations Does Not Begin to Run Until Discovery of Negligence—In 1930 the plaintiff submitted to an abdominal operation in a hospital owned and operated by the Colorado Fuel and Iron Company. The operation was performed by two physician employees of the hospital, but whether the patient paid the hospital for their services or paid the physicians themselves directly the reported decision does not make clear. The patient suffered constant pain thereafter and was attended by various physicians. In October 1940 roentgenograms and fluoroscopes failed to indicate the presence of any foreign body in her abdomen, but a laparotomy performed later in the month revealed the presence in the abdomen of a large gauze pad, which the patient alleged was left there when the abdominal operation was performed. Thus, so the patient alleged, was the first notice that she had had that the physicians had been negligent in performing the abdominal operation in 1930. She sued the hospital, the two physicians who performed the operation in 1930 and a nurse who was in charge of the operating room at the time and assisted the two physicians in the operation. The nurse and the hospital moved to dismiss the action allegedly because the complaint failed to state a cause of action and because an applicable six year statute of limitations in Colorado barred suit. The defendant physicians moved to dismiss because of the bar of an applicable two year statute of limitations. The trial court dismissed the action with respect to all the defendants, and the patient appealed to the Supreme Court of Colorado.

The motion of the nurse, said the Supreme Court, was overruled by the trial court as to the contention that the complaint failed to state a cause of action against her but was sustained as to the contention that the applicable statute of limitations had run. We think the motion should have been sustained as to the first contention—namely, that the complaint stated no cause of action against her. It is not alleged in the complaint that the nurse was derelict as to any special duty with which she was charged, or that she was charged with any. According to the allegations of the complaint she was simply "assisting and surgeons" (referring to the physician defendants), and the presumption is that she was directed by them. Her negligence, if any, was that of the physicians or of the hospital.

The motion to dismiss filed by the hospital was sustained on the grounds that the complaint stated no cause of action against it and that the applicable statute of limitations had run. A hospital, a corporation as here, said the court cannot be licensed to and cannot practice medicine. The relation between physician and patient is personal. That a hospital employs physicians on its staff does not make it liable for the discharge of their professional duty since it is powerless under the law to command or forbid any act by them in the practice of their profession. Unless it employs those whose want of skill is known, or should be known, to it, or by some special conduct or neglect makes itself responsible for their malpractice (and no such allegation appears in the complaint in this case), it cannot be held liable therefor. Hence the motion of the hospital to dismiss because the complaint did not state a cause of action against it was properly sustained. Its motion to dismiss on the second ground, namely, that the applicable statute of limitations had run, becomes immaterial.

The motion of the two physicians to dismiss the complaint as to them was sustained by the trial court on the ground that the applicable two year statute of limitations had run. This, in the opinion of the court, was error. The statute on which the defendant physicians relied, so far as here applicable, reads

No person shall be permitted to maintain an action to recover damages from any person licensed to practice medicine on account of the alleged negligence of such person in the practice of the profession unless such action be instituted within two years after such cause of action accrued.

Much argument has been made, continued the court, on the question of whether it is the negligent act of the physicians or the resulting damage which fixed the date from which the statute of limitations begins to run. We ignore these arguments because that is not the point. The question here is: Does delay due to a patient's ignorance of the cause of a known injury stop the running of the statute when the patient has used every reasonable effort to ascertain the cause and has been frustrated solely by the concealment of the physicians concerned? In other words, under such circumstances, when did the cause of action accrue? There are certain recognized exceptions to the strict and literal construction of such statutes as that here in question, necessarily construed into them by the demands of simple justice and the necessity for evading constitutional conflicts. For instance, it would seem outrageous to deprive one of his right to sue when a superior law forbade suit, or require him to sue when good faith to his debtor forbade action. *Brooks v. Bates et al.*, 7 Colo. 576, 4 P. 1069; *Board of Com'rs of El Paso County v. Flanagan*, 21 Colo. App. 467, 122 P. 801. Do the facts before us constitute such an exception?

Cases involving the applicability of statutes similar to that here in question are numerous, the Supreme Court said, and not a few of them were actions against physicians for leaving a foreign substance in closed incisions. In most of these cases the exceptions are repudiated and the statute strictly construed. A shocking result of this doctrine is well illustrated by a New York case *Couklin v. Draper*, 229 App. Div. 227, 241 N. Y. S. 529; *Id.*, 254 N. Y. 620, 173 N. E. 892, in which a physician performed an appendectomy and left arterial forceps in the wound when it was closed. Despite allegations that he knew of his negligence but failed to disclose it and that plaintiff did everything within reason to discover the trouble and succeeded only when a roentgenogram revealed it and a hasty operation was performed to save life, a two year statute had run and its bar was sustained. A notable "gauze pad case" comes from Alabama, where it was contended that the statute was tolled since the cause of action was concealed by the negligence, hence the malfeasance should be treated as a fraudulent concealment. The strict construction rule was applied but the opinion does recognize the rule that one may not take advantage of his own wrong. A careful reading of the case discloses that the real basis of the decision was the absence of allegations of diligence on the part of the plaintiff to ascertain the cause of his ailment after the performance of the operation in question. *Hudson v. Moore*, 239 Ala. 130, 194 Co. 147.

It is generally held, continued the court, that fraudulent concealment stops the running of the statute. 74 A. L. R. 1320. It is said this is necessary that one be not permitted to take advantage of his own wrong. *Reynolds v. Hennessy*, 17 R. I. 169, 20 A. 307, 23 A. 639. But in such case the defendant has committed two wrongs, the original negligence and the fraudulent concealment. Why permit him to take advantage of the first and apply the rule only to the second? We are not impressed with the reasoning which supports the materiality of fraud. The statute of limitations is enacted to promote justice, discourage unnecessary delay and forestall the prosecution of stale claims, not for the benefit of the negligent. It should not be construed to defeat justice. The negligence is equally damaging and the victim equally helpless regardless of the motive for concealment. This statute has exactly the same effect, in the opinion of the court, as would a contract of employment, which provided that no action could be maintained against the physicians unless brought within two years from the date of the performance of the operation; that is on a par with a contract of insurance providing no recovery can be had unless notice be given within a specified time. Any excuse which would defeat such express contracts is equally effective to toll the statute and it is well settled in this jurisdiction that impossibility to give notice is such. *London Guarantee & Accident Co. v. Officer*, 78 Colo. 441, 242 P. 989; *United States Casualty Co. v. Hanson*, 20 Colo. App. 393, 79 P. 176.

The court then discussed the decision of the Court of Appeals of Maryland in *Hahn v. Claybrook*, 130 Md. 179, 100 A. 83,

86, L. R. A. 1917C, 1169, which, after reviewing with apparent acquiescence various authorities which deny the exception or limit it to other grounds, appeared finally unable to escape the logic and justice of the rule that a patient's lack of knowledge, due to no lack of diligence on his part but solely to a physician defendant's concealment, tolls the statute, and held flatly that "the statute began to run from the time of the discovery of the alleged injury."

It has been held, continued the court, that while generally a plaintiff's ignorance of the wrong committed cannot be considered in determining when the statute begins to run, an exception to this rule is made in cases of the concealment of the cause of action. There the bar of the statute does not operate until discovery, and it is said "This proposition is so fundamental that no authorities need be cited." *Johnson v. Chicago, M. & St. P. R. Co.*, D. C., 224 F. 196, 201. With this statement we agree. Certainly one should not be permitted to take advantage of his own wrong. Under the facts pleaded it was impossible for plaintiff to sue within the limitation and it is a recognized maxim that the law does not require impossibilities. A legal right to damage for an injury is property, and one cannot be deprived of his property without due process. There can be no due process unless the party deprived has his day in court and if without his fault a tortfeasor conceals from him his right until a statute deprives him of his remedy he is deprived of due process. It is also an ancient maxim of the common law that "Where there is a right there is a remedy." What a mockery to say to one, grievously wronged, "Certainly you had a remedy, but while your debtor concealed from you the fact that you had a right the law stripped you of your remedy." Regardless of the number of authorities supporting the rule of strict construction, stated the Supreme Court, we disagree with them on reason and hold that this alleged cause of action against the physicians was not barred by the statute relied on.

For the reasons stated, the judgment of dismissal as to the physicians was reversed.—*Rosane v. Senger*, 149 P. (2d) 372 (Colo., 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Inhibitory Effect of Acid in Intestine on Gastric Secretion.—Pincus and his collaborators performed experiments on 3 dogs equipped with a Pavlov pouch of the stomach and on 1 dog with a Heidenhain pouch. They found that acid introduced into the small intestine of Pavlov pouch dogs inhibits gastric secretion in response to a meal, provided an adequate degree of intestinal acidity is attained. Great inhibition of secretion occurs if the pH of the intestinal contents is about 2.5 and almost complete depression when the pH is 2.0 or lower. The experiments point to the existence of a mechanism for the autoregulation of the gastric secretion which is brought into play when the acidity of the intestinal contents reaches levels which may be harmful to the intestinal mucosa. During the digestion of a meat meal by the dog the acidity of the duodenum near the pylorus is generally near pH 4, while the content of the antrum of the stomach has a reaction between pH 2.0 and pH 3.0. The existence of a threshold level of intestinal pH for inhibition of gastric secretion which these studies show to be within the pH range of the antral contents is suggestive. One of the authors has suggested that the "receptive relaxation" of the duodenum which occurs when the stomach empties itself results in the accumulation of duodenal contents in the vicinity of the pylorus. Occurring at the moment of exit of the acid gastric contents, this would facilitate quick dilution and partial neutralization of the chyme (to about pH 4.0). It may now be supposed that, should this neutralizing ability of the duodenal contents be ineffective, a second mechanism may be set into action, one which arrests the secretion of the acid at its source. The intestinal phase of digestion is believed to give rise to a corresponding intestinal phase of gastric secretion. The suggestion has been advanced that the intestinal phase of gastric secretion is normally regulated to some extent by the acidity-

of the intestinal contents. The results obtained by the authors cast doubt on this assumption. In the dog, at least, little inhibition of acid secretion occurs if the intestinal pH is above 2.5. Acidities as great as this are rarely found in the dog's intestine. The authors regard this mechanism as one which is set into action only during emergencies when other means of reducing the acidity of the intestinal contents have failed. The possibility remains that in man the threshold is higher than pH 2.5, which would explain the results of Griffiths and Shay et al., who used less concentrated solutions of acid. The inhibition observed in these experiments may be due to enterogastrotrone; the intestinal instillation of acid failed to inhibit the gastric secretion provoked by histamine.

Histidine in Allergy and Shock.—Ruskin experimented with a viable section of a bronchiole from rabbit lung obtained according to a slightly modified technic of Sollmann and Gilbert. The purpose of the experiment was to produce contraction of the bronchiole by adding histamine hydrochloride to the Ringer-Locke-dextrose solution to obtain a 1:50,000 concentration. After the contraction due to the histamine was established, and at a fixed interval, the substance to be tested for histamine antagonism was added. It was demonstrated that vitamin C has slight histamine antagonism in itself, but when serving as the acid radical for calcium, epinephrine, amphetamine or epinephrine it enhances their histamine antagonism and bronchiole dilating capacity. This is important in increasing respiratory ability. Calcium gluconate not only did not antagonize histamine hydrochloride but actually increased contraction of the bronchiole to the drug. Calcium ascorbate, on the other hand, antagonized histamine, and the response was quicker than that to either vitamin C alone or sodium ascorbate. This is significant in view of the conflicting claims made for calcium in the treatment of asthma. The synergistic effect of vitamin C on calcium may be the all deciding factor in the therapeutic value of calcium in allergy. Calcium gluconate may produce unfavorable results in the treatment of asthma, while calcium ascorbate may be useful. While amphetamine ascorbate produced a quick recovery from histamine contraction, with strong histamine block, the amphetamine sulfate showed no histamine antagonism and in fact prolonged histamine contraction. The implications of this experiment may be important in relation to histamine shock. While amphetamine sulfate can keep a soldier alert, it may predispose him to greater histamine shock, whereas the vitamin C salt may protect against histamine shock. The epinephrine ascorbate showed about twice the bronchiole dilating capacity exerted to epinephrine hydrochloride and a much quicker and more active histamine antagonism. The amino acids histidine and tyrosine, supplemented by methionine and choline, serve as fundamental factors in the balance between histamine and epinephrine. The author arrives at the following conclusions: (1) Therapeutic usefulness of the amino acid histidine is indicated in allergic and related conditions; (2) histidine is antagonistic to histamine and plays an important part in histamine-epinephrine balance in shock; (3) histidine produces a feeling of well being and energy that could be useful in the care of postoperative patients and the treatment of shock. Further study of histidine enrichment of parenterally administered protein hydrolysates as blood substitutes is being conducted.

- Collapsive Therapy in Pulmonary Tuberculosis R D Thompson —p 16

Rupture of Coronary Artery—A man aged 74 was hospitalized with the complaint of tightness in the abdomen and shortness of breath. These symptoms came on gradually and grew worse. Six days previously he had been seized with a pain across the back which radiated up the neck to both jaws and down both arms, lasting ten minutes, four days before admission he had been kept awake most of the night with similar pains. The pulse could not be felt. The systolic blood pressure appeared to be about 50. Oxygen was administered and morphine was given twice during the night. The patient continued to have severe dyspnea and died the next morning. At necropsy the pericardial sac contained about 650 cc of liquid and clotted blood. On the anterior surface of the left ventricle, adjacent to the anterior descending branch of the left coronary artery there was an irregular tear in the epicardium with a small blood clot extruding. The coronary artery was sclerotic and calcareous, and there was a rupture of the artery with clotted blood in the opening. Dobbin states that the literature contains reports of only 33 cases of death due to rupture of a coronary artery.

Leukemia Complicating Pregnancy—Applebaum reports a case in which myeloid leukemia developed during the first half of pregnancy. Three blood transfusions produced prompt but short lived improvement. A month later the woman, aged 29, was hospitalized again and was given x ray treatments and blood transfusions, in spite of some improvement the course was steadily downhill. Since the patient would take no food, and nausea and vomiting became persistent, dextrose and saline solution together with amino acids were started intravenously, vitamins were given parenterally, all to no avail. A cesarean operation was performed in the hope of saving the child and giving some relief to the patient. The fetus was found dead, and the mother expired several hours later. Microscopic examination of the organs of the fetus revealed no leukemic infiltrations of the lymph nodes or spleen or of any of the 23 sections taken from the various organs. The absence of leukemia from the fetus is another link in the chain of evidence that 'a leukemic mother has never given birth to an infant with leukemia'. This suggests that leukemia in man is probably not transmitted by the mother to the child.

Aseptic Necrosis in Caisson Workers and Others—Taylor observed 54 persons showing aseptic necrosis and bone infarcts. Of the 13 patients who had worked under compressed air for varying periods of time some were subjected to sudden changes of atmospheric pressure and had experienced symptoms of acroembolism decompression illness or bends. Others were not subjected to sudden changes in atmospheric pressure. Of the latter group some had mild or subacute symptoms of decompression illness and others did not. Shaft and joint lesions do not develop immediately after decompression illness. Considerable time must elapse. The shaft lesions are usually asymptomatic and are discovered accidentally. In the joints secondary arthritic changes occur resembling a chronic hypertrophic osteoarthritis. The lesions observed in the 41 patients who had never worked under compressed air and had never been subjected to sudden or violent changes in atmospheric pressure were similar to those in the occupational group. In the caisson worker the etiologic factor is the presence of an inert gas, nitrogen, in bubble formation either forming an embolus or producing pressure or both, thus interfering with the circulation to the part. In the noncaisson worker there is no apparent etiologic factor. The bone lesions may be single, though usually they are multiple and often bilateral. Caisson workers presented extensive and multiple lesions more often than others. In the noncaisson worker, in whom the lesion is single and not extensive, the reparative changes are usually greater. Deep sea divers and aviators may develop acroembolism. There are, however, no recorded evidences of bone changes in either naval or air personnel who have had attacks of acroembolism.

Accidental Trauma and Tumor Metastasis—Loth presents 2 cases of generalized carcinomatosis which were studied with a view of determining the influence of mechanical injuries on the formation of metastases. He lists the requirements that, according to Second Thiem Lubarsh and Living should be fulfilled to establish a relationship between injury and tumor. He evaluates his 2 cases with these requirements in mind. Lacerations of the skin, repeated subcutaneous and intravenous injections, surgical amputation of the forearm, and linear as well as compression fractures failed to result in the localization of secondary tumors. One post-traumatic and several supposedly post-traumatic metastases seemingly fulfilled all the requirements of Second for the establishment of a definite relationship between accidental injury and metastatic cancer. On further observation, however, it became evident that this patient had an unusual type of metastatic spread from a primary lung carcinoma with preterential involvement of the subcutaneous tissues and muscles. The practically identical appearance of several intramuscular and subcutaneous metastases was evidence against a traumatic influence. A subsequent experimental blunt traumatization affecting mainly the subcutaneous structures in an apparently favorable location failed to result in the formation of a metastasis.

tasis. It thus appears that the unknown laws of metastasis have had an overwhelming—probably an exclusive—influence in the localization of the secondary deposits, possibly being entirely indifferent to the incidental presence of multiple traumas. The author suggests that in cases which are doubtful from the medicolegal point of view a further requirement should be added to the usual postulates of Segond and others.

Deaths from Sulfonamides.—Gessler studied tissues from 3 patients in whom death is believed to have been caused by sulfonamide administration. The major cause of death in all 3 cases was uremia, but in 1 case a previously undescribed type of pulmonary pathology was believed to be an important factor. In 2 cases sulfathiazole was the drug used, in the third case sulfadiazine was used. The author presents clinical histories, postmortem observations and the results of microscopic studies. In 1 case, in addition to tubular nephritis, myocarditis and visceral focal necrosis, a previously undescribed interstitial pneumonitis with hyaline membrane formation was found. The author reviews 30 cases from the literature. In these sulfathiazole was the incriminated medication 16 times, sulfadiazine 5 times, sulfapyridine 6 times and sulfanilamide 3 times. Anuria was the complicating factor in 18 cases, the majority of which were treated with sulfathiazole. Agranulocytosis was the complicating factor 5 times, agranulocytosis was not found in sulfadiazine treated cases. Hemolytic anemia was the complicating factor once, sulfanilamide was used then. In the other 6 cases death was not due to drug intoxication, but signs of drug intoxication were incidental findings of the necropsy. The urinary tract was blocked by concretions of the drug in 3 cases, a different drug was used in each of these cases. In 11 cases there were evidences which suggested that there might be a blocked urinary tract, most of these were in sulfathiazole treated cases. Uremia and agranulocytosis are the most frequent lethal complications. The mechanism by which the sulfonamides cause toxic symptoms has not been completely explained. There are many uncorrelated facts which require further study. It seems likely that many of the minor reactions—nausea, dizziness, disorientation, headaches—may be due to the allergic or pharmacologic reactions, kidney damage and hematuria are apparently due more often to mechanical factors. Focal necrosis, agranulocytosis and periarthritis nodosa may be due to a combination of these factors. Although most physicians view with alarm the appearance of one or more of the minor reactions while patients are receiving sulfonamides, there is little evidence to suggest that the minor reactions are precursors of the more serious reactions.

Clinical Analysis of 1,000 Cases of Low Back Pain.—The scope of this paper by Jelsma is limited to the consideration of those cases in which pain is complained of in the lower lumbar region especially with distribution of pain along the sciatic nerve. A total of 531 of the patients had sufficient clinical signs and symptoms to warrant the assumption that a focal neurologic lesion was present. It was found that 484 of these 531 patients had clinical signs to warrant the diagnosis of probable herniated disk. Of the remaining 47 patients with symptoms of neurologic focal lesions 10 had crushing of one or more of the lumbar vertebrae, 10 had a metastasis to the lumbar spine, 9 had primary intradural tumors, 9 had spina bifida occulta, 4 had spondylolisthesis, 4 had sacralization of the fifth lumbar vertebra and in 1 patient the symptoms were due to an arachnoid cyst. In many of the 469 cases in which focal neuro-

logic signs could not be found the pain was apparently due to hypertrophic arthritic changes. In view of the abundance of nerve endings found in the posterior longitudinal ligaments, it has been suggested that the cause for many low back pains, without other evident causes, is due to involvement of the disks without protrusion and without compression of the spinal nerves. McKenzie feels that destructive processes of the disks (traumatic or otherwise) can produce such pains. This group of patients was treated with palliative measures. Palliative measures were used for all patients with herniated disk as long as it gave improvement. The surgical mortality rate was zero.

Effect of Plaster Confinement Applied at Varying Intervals After Burning.—Ulrich and Lehman made studies on dogs to determine the effects of plaster confinement applied at varying intervals following a standard burn on the composition of the circulating blood and lymph from the burned area. Data were also obtained on the local effects of this form of treatment. It is important to distinguish between plaster confinement of a burn and pressure dressing. It is conceivable that pressure dressings applied late might be effective in returning some of the extravasated plasma to the blood stream, a result not to be anticipated with simple confining dressings. The experiments tend to substantiate the hypothesis that confinement of a burn in a cast protects the circulating blood volume. They also suggest that the time of application of the confining dressing is of major importance. From the point of view of preventing plasma loss this type of dressing, therefore, is not perfectly adapted to the care of clinical burns that are treated more than an hour or so after injury. Since, however, there is evidence that local tissue loss is decreased, the use of this treatment is not contraindicated. Whether or not pressure dressings, in contradistinction to simple confining dressings, are effective in returning already extravasated plasma to the circulation is not shown by this study.

Vasoconstrictor Substance in Lymph from a Burned Area.—This study by Ulrich offers evidence of the existence of a vasoconstrictor substance in the lymph from a burned area. Dogs under usual laboratory conditions were employed, divided into control and experimental animals. The latter were subjected under pentothal sodium anesthesia to a standard hot water burn of a paw according to the method of Glenn, Peterson and Drinker. In both groups a lymph vessel leading from the paw was cannulated and samples of lymph heparinized as the fluid entered the cannula, were collected. In the burned animals the lymph flow was spontaneous, in the control animals mechanically effected passive motion of the paw was necessary to obtain adequate samples. Hourly samples of lymph were obtained for study and were passed through the perfused rabbits ear in varying amounts. The presence of a vasoconstricting substance was indicated by a decrease in the electrically recorded drop

rate from the ear vein. Since vasoconstrictor substances are developed in the process of coagulation, both the control and the experimental observations were carried out on previously heparinized as well as on normal dogs. The reported experiments give evidence of a vasoconstricting substance in the lymph from an experimentally burned area. It is not due to the process of coagulation, since it is present when previously heparinized animals are employed. It is possible that this is the constrictor substance observed in the circulating blood by Page. The substance has not been identified nor its relation to a supposed "burn toxemia" established.

Gynecomastia.—Seven cases of gynecomastia, are reviewed by Goccl. Endocrine influences and trauma are probable etiologic factors. Only 1 patient presented any semblance of endocrine dyscrasia. Three patients in this series mentioned the possibility of trauma when questioned closely, but only 1 was definite. Gynecomastia may be confused clinically with chronic mastitis. It is difficult to predict preoperatively exactly what pathologic change has occurred. Gynecomastia may be underlying, but mastitis or neoplasm may be contributory. Metaplasia in an intraductal papilloma was found in 1 case in this series. All patients in this series were treated by mastectomy. All were healed and ready for full duty in from ten days to three weeks. The surgical approach was through a slightly curved, transverse incision made just inferior to the areola. This permitted easy dissection of the areola and nipple from the breast without injury, offered approach to all portions of the breast including the axillary prolongation and permitted a cosmetically desirable closure without distortion of the areola. The entire breast was excised. This apparently is important, since only a portion of the left breast in 1 case had been removed at the first operation, following which symptoms continued.

Autoplastic Sutures in Inguinal Hernia.—Chiles and Lenhardt point out that the use of fascial strips for the repair of inguinal hernia was advocated more than four decades ago by McArthur. The type of hernia repair advocated in this paper is based on the technic of Robins, who in 1938 reported his results with the use of autoplastic sutures in hernia repair. The authors describe the operative technic and stress the following points: 1. The careful separation and identification of the various abdominal layers will not only facilitate the operation but also allow the structures to fall into their new relationship after suturing. 2. Fascial sutures are resistant to infection; they do not tear and are not absorbed. 3. The stress or strain is not all on the terminal end of the suture, but it is applied

after the principle of a windlass, being equally distributed throughout the course of the suture. 4. The existing pathologic condition should be the guide as to the type of repair to be used. 5. When for any reason the external oblique muscle is inadequate, the fascia can be secured from the fascia lata of the leg by the use of a Masson stripper.

Temporary Stimulation of Emmetropic Visual Acuity.—Lebensohn and Sullivan say that visuopsychic excitation seems to be the only factor common to the procedures recommended for improving natural vision. An increase of interest, attention and alertness effects keener interpretation of visuosensory stimuli. Drugs that accelerate cortical or sympathetic activity should be effective. This view is supported by recent experiments on one of the fundamental measurements of visual function, the fusion frequency of flicker, which is indicative of the excitability of the visual system. An increase of acuity above that attainable by a careful refraction would emphasize how much the psychic cortex participates in visual acuity measurements. Fifty men were selected for study whose visual acuity in each eye was 20/20 or better, naturally or with glasses. Acuity was tested on the double broken circles of the Ferree-Rand chart. From a stop watch record of the ten letter reading, the speed per letter in tenths of a second was noted and the average of three trials recorded. In every subject the eyes were examined separately and binocularly, so that each examination involved three tests for speed and acuity respectively. Each man was tested at 8 a. m. and was then given a placebo as a control or 10 mg. of amphetamine or 3 cc. of nikethamide, and the tests were repeated at 10 a. m. and 2 p. m. A consistent improvement in acuity and reading speed was induced by nikethamide and amphetamine in both slow and fast readers. Nikethamide or amphetamine improves reading speed more than visual acuity, but the effect of amphetamine on both visual functions is more pronounced than the effect of nikethamide. Analysis of 150 tests shows that in 44 cases amphetamine was relatively superior to nikethamide in stimulating visual acuity and in 126 cases in increasing reading speed. Amphetamine apparently exerts a more beneficial influence on normal than on ametropic vision. This was proved by comparative tests on 16 persons with ametropia. The authors conclude that the psychogenic origin of many visual complaints is probably insufficiently appreciated. The visuopsychic cortex can be stimulated by various measures, but amphetamine in small doses (from 5 to 10 mg.) is a simple, safe and efficient agent for this purpose.

Book Notices

Intravenous Anesthesia. By R. Charles Adams, M.D., C.M., M.S., Associate in Section on Anesthesiology, Mayo Clinic, Rochester, Minnesota. Cloth. Price, \$12. Pp. 663, with 75 illustrations. New York & London: Paul B. Hoeber, Inc., 1944.

This monograph covers the development of intravenous anesthesia from 1872 until the present time. It includes chapters on chloral hydrate, hedonal, ether, isopral, paraldehyde, magnesium sulfate, morphine, alcohol, tribromoethanol, somnifene, local anesthetics, allylisopropyl barbituric acid (alurate), phenobarbital sodium, dial, pernoston, sodium amytal, pentobarbital sodium, evipal soluble, pentothal sodium, miscellaneous derivatives of barbituric acid and analeptics. Each of these subjects is introduced by a concise consideration of the historical data. This is followed by a consideration of the chemistry, pharmacologic action and clinical use. So completely is each subject treated that the book will be very useful for clinicians and teachers. A practically complete bibliography of references (3,489) makes this book valuable for research workers.

Much effort was expended by the author and those who assisted him in clarifying the confusion which has existed regarding the names of the many derivatives of barbituric acid. To the anesthetist the value of this book is apparent. General practitioners, who use intravenous anesthesia only occasionally, can quickly obtain information about the action, the dangers, the dose and the method of administration of the drugs that are used for this purpose. An exhaustive consideration of pentothal sodium, which is at the present time the most useful and available of the derivatives of barbituric acid for intravenous use, is presented. The concluding chapter, on "Use of Intravenous Anesthesia and the Barbiturates in Military Surgery," indicates the timeliness of the book.

Commendation of the author for the great effort which obviously was made in compiling this book, as well as its recommendation to all persons who have occasion to use or to study the drugs which are used intravenously is made after reading this valuable work, which is very well done.

Fractures and Joint Injuries. By R. Watson-Jones, B.Sc., M.Ch.Orth., F.R.C.S., Consultant in Orthopedic Surgery to the Royal Air Force. Volumes I and II. Third edition. Cloth. Price, \$18 per set. Pp. 407; 409-960, with 1,353 illustrations. Baltimore: William Wood & Company, 1943.

Mr. Jones is civilian consultant to the Royal Air Force on fractures and dislocations. He travels from one end of the British Isles to the other by air, by train, by bus, setting up fracture hospitals for R. A. F. fliers. He not only sets up the hospital but consults with the local hospital surgeons regarding treatment. He personally supervises and operates in some of the difficult cases. Mr. Jones is well known in the United States and Canada. He is especially well known to orthopedic surgeons and to traumatic surgeons, especially those who deal with fractures and dislocations. Because of the large number of additions, this edition has been published in two volumes. More books like this are needed; that is, books that are based on (1) large experience, (2) careful study of the subject and (3) good judgment not only in diagnosis but in treatment.

The material is well selected, the composition is excellent and the sequence is proper. The illustrations consist of line drawings, photographs, x-ray reproductions, diagrams, color figures and "peep" illustrations. "Peep" illustrations are those which permit the reader to make a diagnosis from the illustration and then flip a flap covering another nearby illustration, thereby uncovering the correct diagnosis. Many of the diagrams, such as those illustrating blood supply to various sections of bones, such as the ankle bones and the leg bones, are in color.

There are many excellent features in the book, from the standpoint both of basic principles of diagnosis and treatment and from that of specific diagnosis and treatment. (Some will consider Jones radical in several instances.)

The author states that the first edition of his book on fractures and joint injuries was written under the threat of war, the second with the realization of war and the third after the experience of war. The writing of many pages has been disturbed by the fall of bombs and the crash of timber. Manu-

script has been destroyed by the effect of fire and explosion. His proofs have been delayed by the emergency of casualty surgery.

The author has had a tremendous experience. In former editions he stated that he had experience with nearly 50,000 civilian casualties, for example in the first two years of the war 75 cases of dislocation of the astragalus have occurred in the Royal Air Force Medical Service.

Every chapter has been revised, new sections have been added on open and infected fractures, war wounds, sequestrectomy, vascular injuries, immersion foot and shelter foot, traumatic edema and the crush syndrome, gangrene due to tourniquets, Volkmann's ischemic contracture, traumatic asphyxia and chest injuries, avascular necrosis of the hip joint, distraction of fractures, radiographic diagnosis of union, internal fixation of fractures, no-touch technic, treatment by lay-on grafting, burns and contractures of the hand. New recommendations have been made in the treatment of supraspinatus tendon injury, and various fractures and dislocations of the upper extremities. He describes methods of treatment for acromioclavicular dislocation and supracondylar fracture of the femur. The author is very strong for rehabilitation centers. It is evident that rehabilitation is the watchword of the hour. Treatment is concentrated not only on the union of fractures but on the function of limbs, not only on surgery and manipulation but on gymnastics and recreation, not only on the relief of disability but on the cure of psychologic disorders. This is the most striking development of fracture treatment in recent years, and a special chapter is devoted to its consideration. The new addition has over 200 more pages than the early editions and therefore was published in two volumes. The expansion is due largely to added roentgenograms, diagrams and photographs. There is one interesting quotation which reads "My story is not long but it took me a long time to make it short," credited to Thoreau. Jones emphasizes the fact that a fracture is not to be labeled ununited simply because union is incomplete in a specific number of weeks or months. He emphasizes the prevention of edema of the leg.

One of the striking features of the book is the chapter on vascular injuries complicating wounds and fractures. Another section of importance is on the danger of x-rays to surgeons. He recommends the use of Unna's paste dressing to prevent edema after the removal of a plaster of paris cast of the leg. There is a good section on the complications of plaster immobilization. There is another on the indications for operative reduction. The second on scrupulous aseptic technic is well worth reading. There is an excellent section on open and infected fractures in war wounds. Over 40,000 amputations were performed in England during the last war and during the few years immediately following. Since then tremendous strides have been made in the surgery of wounds in compound fractures, and amputations are becoming increasingly rare. For example, in one large series of casualties treated in R. A. F. base hospitals, the incidence of secondary amputation or spreading infection, gas gangrene, secondary hemorrhage and other complications was as low as 0.1 per cent despite a high proportion of severely infected and grossly contaminated wounds and compound fractures.

There is a large number of references, and it is remarkable how many of Mr. Jones's own contributions have been made to the subject at hand.

Cancer: A Manual for Physicians. Published jointly by Michigan State Medical Society and Michigan Department of Health. Cloth. Pp. 225. Lansing, 1944.

This book is written by members of the Michigan State Medical Society under the editorship of its cancer committee. The Michigan Department of Health contributed toward the expenses of publication. Like that of similar books in other states, its purpose is to "assist the physician in making his diagnosis of early cancer and in reaching his decision as to the type of therapy to be employed, without subjecting the patient to the dangerous delay that sometimes occurs." There are forty-four unsigned articles by thirty-eight authors. These articles deal with the general and special aspects of cancer, including tumors of the brain and of bones. The articles are

of course short but as a rule cover their topics well. The articles on biopsy in tumor diagnosis and on radiotherapy of cancer are especially praiseworthy. The statement about grading of cancer in the first of these articles merits quotation: "Many physicians attach far too much importance to the numerical grade of neoplasms. It must be kept in mind that the grade is assigned by the pathologist only in accordance with his impression of the level of differentiation. By itself, the grade tells nothing about the clinical state of the patient, nor does it indicate the prognosis. A grade 1 carcinoma may have been present for many years and may have spread widely by both infiltration and metastasis. It may still be grade 1 when the patient is about to die from its effects. Conversely, a grade 4 carcinoma may be so early and so small that the patient can be cured by a single sweep of a curet. Type of neoplasm, location, extent, duration and metastasis, as well as grade, determine the prognosis." It may be mentioned also that the fundamental principles of treatment remain the same whatever the grade. The article on carcinoma of the larynx is utterly inadequate, because it does not even mention its treatment with external radiation, which is now the treatment of choice of certain forms of laryngeal cancer. There are instructive articles on occupational cancer, on tumors of the endocrine glands, on the care of the patient with advanced cancer, on the Michigan program, on lay education and on cancer from the general practitioner's point of view. "The most worthwhile service the general practitioner can render his patients who may have cancer is in prompt initiation of the processes through which they will obtain the best diagnostic and therapeutic services possible."

The Compleat Pediatrician: Practical, Diagnostic, Therapeutic and Preventive Pediatrics for the Use of Medical Students, Interns, General Practitioners, and Pediatricians. By Wilbur C. Davison, M.A., D.Sc., M.D., Professor of Pediatrics, Duke University School of Medicine, Durham, North Carolina. (Adaptation of the Title Page of the Compleat Angler by Izaak Walton, 1653.) Fourth edition. Cloth. Price, \$3.75. Pp. 256. Durham: Duke University Press, 1943.

Few books on pediatrics have had the widespread acceptance as *The Compleat Pediatrician*. The fourth edition of this excellent guide and compilation of pediatric facts is current and well edited. Practically all important contributions to the field of pediatrics since the text was last revised three years ago are included in the present edition. Sections on chemotherapy, tropical diseases and infectious diseases have received particular attention, but almost every part of the book has been brought into line with recent work. The book has always enjoyed a merited reputation for its vast amount of practical pediatric facts in the most concise and readable form. Few books dealing with pediatrics are as current and as well edited. Practitioners have always shown a preference for the previous editions, and it has served them well in their practical work. The last few editions have found an increasing acceptance among medical students, who have found it invaluable on their pediatric clerkships. The author's extensive experience as scientist, clinician and educator is reflected in its pages, and few books on pediatrics are as authoritatively edited and as convincingly presented.

Polish School of Medicine at the University of Edinburgh. Editor: Józef Brodzki. Cloth. Pp. 62, with 24 illustrations. London & Edinburgh: Oliver and Boyd, Ltd., 1942.

This little volume tells the exciting story of a unique event in scientific history. Never before has any state set up its own medical school with its own professors teaching its own students in their native tongue on foreign soil and as a part of a foreign university. A considerable part of the Polish army was evacuated to Great Britain on the fall of France in June 1940. Included were several hundred medical officers, among whom were teachers, physicians and scientists of high professional standing. There were also numbers of recent medical graduates and men who had completed part of their medical training in Poland. The University of Edinburgh magnanimously offered its facilities, the Polish government in exile provided financial support and the Polish School of Medicine at the University of Edinburgh was organized. It opened its doors to Polish men and women, officers and civilians. March 22, 1941. Facilities provided by the University of Edinburgh

include the use of lecture theaters, tutorial rooms, hospital wards, laboratories, instruments and reagents, microscopes, specimens, slides and films. The faculty includes fourteen former professors in Polish medical schools in addition to ten physicians without former academic connections. During the first year of operation there were seventy-nine students at various academic levels. Medical degrees were conferred on nineteen students during the second academic session. The faculty has contributed to scientific meetings and has published significant scientific articles on the basis of investigations conducted at the new school. This school represents not only the true international spirit of medicine but also the courage and persistence of Polish medicine and education and will provide an important beginning for the rebirth of medicine in Poland, which has now been reduced by the Germans to an "intellectual desert."

Human Constitution in Clinical Medicine. By George Draper, M.D., Associate Professor of Clinical Medicine, College of Physicians and Surgeons, Columbia University, New York, C. W. Dupertuis, Ph.D., Physical Anthropologist, Consultation Clinic, Presbyterian Hospital, New York, and J. L. Caughey Jr., M.D., Med.Sci.D., Associate in Medicine, College of Physicians and Surgeons, Columbia University. Cloth. Price, \$4. Pp. 273, with 29 illustrations. New York & London: Paul B. Hoeber, Inc., 1944.

This book is designed primarily for students, to give them an insight into the human constitution as it plays a role in clinical medicine. However, the practitioner will find it exceedingly interesting even though he will have to review some of his basic sciences to understand much of the discussion. From the cultural point of view it is a healthy addition to medical literature, but from a practical standpoint one seriously questions the need for such exact measurements of a group of patients with pernicious anemia, duodenal ulcer, acute rheumatic fever, migraine, toxemia of pregnancy, gallbladder disease, carcinoma of the breast and carcinoma of the uterus. It is hoped that the authors in teaching this material to their students do not hold them too strictly accountable for the details of the textbook but teach the course with the distinct impression that it is something they have been vitally interested in, and they are now happy to give to their students and the medical profession a field in which they have had an interest.

Secretory Mechanism of the Digestive Glands. By B. P. Babkin, M.D., D.Sc., LL.D., Research Professor of Physiology, McGill University, Montreal, Canada. Cloth. Price, \$12.75. Pp. 900, with 220 illustrations. New York & London: Paul B. Hoeber, Inc., 1944.

All students of gastroenterology are familiar with "The External Secretions of the Digestive Glands," written in lucid German and extraordinarily well documented by Dr. Babkin. The present volume constitutes another important contribution to gastroenterology. The subject matter deals principally with the mechanisms which are concerned in the regulation of the secretory activity of the digestive glands. It does not cover the older literature, which was adequately covered in the preceding book. It presents a critical review and summary of the work done since 1929 by the author and his students and the contemporary work of other investigators in the field. However, adequate reference to older work and comprehensive reviews is not lacking. A copy of this book should be in every medical library, and graduate students in the field of digestion will have to use it and will be thankful for having it available. Dr. Babkin and the publishers in providing this volume have rendered a definite service to physiology and medicine.

Occupation and Health: Encyclopaedia of Hygiene, Pathology and Social Welfare, Studied from the Point of View of Labour, Industry and Trades. Special Supplement: Industrial Health in Wartime. Paper. Price, 25 cents; 1s. Pp. 29. Montreal: International Labour Office, 1944.

Industrial Health in Wartime reviews recent pertinent literature under headings of silicosis, metal poisoning, insecticides and fumigants, carbon monoxide, carbon disulfide, benzene and its homologues, explosives, rubber, chlorinated naphthalenes and diphenyls, radioactive luminous paints and x-rays, toxic limits, caisson sickness, hygiene in aviation and skin diseases, over the signature of Dr. Ludwig Teleki. Bibliographies are attached to each chapter and contain references for the period 1940-1942. A short general bibliography is also included.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

POSSIBLE HAZARDS FROM FILARIASIS IN THE UNITED STATES

To the Editor:—Recently I was reading an article on filariasis by James T. Culbertson, Ph.D., in the July issue of the *American Journal of Nursing*. In this article it is implied that there is a definite danger of transmission of this disease from returned veterans infected with it to healthy persons in the United States, including New England, because infection is spread through the common house species of mosquito. This is a definite industrial problem because not a few of these men are working in schools learning welding with our native population in areas where mosquitoes are prevalent. Will you kindly let me know just the extent of this hazard and whether or not any preventive measures could be or should be taken.

David W. Parker, M.D., Manchester, N. H.

ANSWER.—Dr. Culbertson, in the article referred to, states that "with an abundance of suitable mosquito vectors available almost everywhere in this country, the transfer of the infection to native Americans, not only from these infected immigrants but also from the returning infected service men, seems possible and poses a problem to which public health authorities must give careful scrutiny."

The transmission of filariasis from returning infected troops is possible but probably will be exceedingly rare for a number of reasons. The transmission of filariasis by mosquitoes is somewhat hazardous to them. Heavy infections may result fatally to the mosquitoes. Further, there is no multiplication of the parasite in the mosquito as there is in malaria; hence the mosquito must secure from human blood a larva for every worm it transmits to a new victim. Further, it is believed that the infectious larva is not injected into the blood stream of man by the mosquito but is merely deposited on man's skin and must make its own way into the blood stream. These factors militate against transmission from man to man. In many parts of the United States, although mosquitoes are considered to be a pest and are certainly abundant, their numbers do not begin to approach those found in heavy filaria infected areas. It is possible, however, that through a fortuitous combination of all circumstances a mosquito might bite an infected person in this country and live to reinfest another person.

A number of years ago a large group of Negroes from a filaria infected area were imported into Charleston, S. C. Because of the climate there, mosquitoes can breed much of the year and in the early days before mosquito control they were unusually abundant. Thus the unusual combination of a large number of filaria infected individuals and a large number of mosquitoes much of the year resulted in the transmission of filariasis to a considerable number of persons in Charleston. A survey made there by Johnson in 1915 of 400 individuals composed largely of routine hospital admissions revealed an infection rate of 19.25 per cent. Within the last few years control measures to eliminate mosquitoes in the Charleston area have been pushed vigorously, and the screening of homes has become much more common. For these and possibly other reasons the transmission of filariae in the area has practically ceased and no new infections have occurred in Charleston in the past few years. In other words, the infection is dying out. If under the more or less ideal conditions of climate and a large initial infection this disease died out in Charleston, it does not seem likely that it will spread in the Northern areas of the United States, where mosquitoes are found in numbers only during the hot summer months.

Filaria infected persons have been reported from Columbia, Beaufort and Georgetown, S. C., Jacksonville, Fla., and Mobile, Ala. (Francis), Philadelphia, (Flint) and Boston (Lothrop and Pratt). These persons all give a history of having lived in Charleston, S. C., or having come from a filarial area in the tropics. No endemic foci or secondary cases arising from these infections have been reported, although the climate of several of these areas is favorable for mosquitoes and they are found in considerable abundance. In recent years thousands of Puerto Ricans and inhabitants of other infected Caribbean countries have entered the United States and made their homes here. A number of these individuals harbor large numbers of microfilariae in their blood but do not appear to have been the cause of additional cases of filariasis in this country.

On the other hand, filaria infections have been reported in individuals who have never been to Charleston, S. C., or out of

the United States. Dunn reports such an infection in Philadelphia, Slaughter two from Richmond, Va., and Mastin one from Mobile, Ala. Presumably these infections were acquired in these areas.

It is believed that the evidence at hand can be summarized as follows: It is remotely possible that returning filaria infected individuals may transmit, through mosquitoes, their infection to other individuals in this country. This occurrence, however, is extremely unlikely, and although the possibility must be borne in mind, it does not appear likely to be of any great importance.

QUARANTINE FOR POLIOMYELITIS

To the Editor:—The distant poliomyelitis invaded area (Louisville, Ky., and Charlotte, N. C.) has our local school board in a quandary. Owing to pressure of a citizen, the school board has passed a resolution to quarantine all students and teachers who are not in the county. Actually the board intends to prohibit bath from attending school until they have been in the county two weeks. This does not effect a quarantine, because all are free to mingle when school is not in session and may contact one another at picture shows or other places. On the surface of it the effort seems to void itself before it is put in effect. As a physician I suggest that, until the poliomyelitis problem is solved, all that is reasonable to do is to put into effect the well known rules of communicable diseases, namely, isolate the victim, quarantine those exposed. It seems rather arbitrary to rule a blanket quarantine. A county line has nothing to do with where or whether a person contracts a disease. A restriction of this kind certainly works hardship and extra expense (for teachers to pay board and the like) without accomplishing its purpose. So far as I know no student or teacher is coming here from the area around Louisville or Charlotte, yet all must be kept out of school until they have been in this county two weeks. Will you give me same statement as to whether the health rules known to all, as mentioned, are enough to use as a guide in handling this problem? Your recommendation will be appreciated, owing to the fact that the board's action seems rather radical.

M.D., Florida.

ANSWER.—There is no evidence that rigid quarantine of age groups is of any effect in the control of the spread of poliomyelitis. This but tends to spread panic and fear. There is no scientific reason for prohibiting persons from attending school until they have been in the county for two weeks. Most public health authorities agree that even in the presence of an epidemic there is no reason for not opening schools.

FLUORIDE FOR THE PREVENTION OF DENTAL CARIES

To the Editor:—I have been following the discussion on the advantages of fluoride in the prevention of dental caries and should like to obtain an authoritative opinion as to the practicability of using it as a prophylactic measure. What are the practical hazards, and why is it not being used more widely in private practice?

M.D., Massachusetts.

ANSWER.—The use of fluoride in the prevention of dental caries is in the experimental stage. A large amount of epidemiologic evidence shows that children who have used continuously since birth a domestic water containing as little fluoride as 1 part per million have only about one-third the amount of dental caries of children who have used a fluoride free water. This observation points to the probability that low fluorination of the public water supply may achieve an appreciable degree of mass control of dental caries. Several long term studies (ten to fifteen years) are being planned to test this hypothesis by fluorinating selected fluorine free city water supplies. Faust has recently estimated the cost of raising a fluorine free water supply to 1 part per million as 7.5 cents per person annually. Such control procedures would presumably be of value only to those born subsequent to the low fluorination of the public water supply, e. g. those who calcified their teeth while using a water with this optimal concentration. Whether or not such procedures would be effective in inhibiting dental attack in persons whose permanent teeth are erupted awaits further investigation.

Other investigators have directed their attention to topical application of fluoride in order to learn whether or not post-eruptive fluorine therapy can be utilized as a prophylactic measure for (a) that third of the population dependent on private

wells or other supplies for their source of water and (b) that part of the population whose permanent teeth have already erupted.

Several studies along these lines involving groups of school children have been reported. In each an appreciable reduction in the incidence of dental caries has been reported following multiple application of relatively high fluoride concentrations. In one study involving young men in a military population no change in dental caries attack was observed following a single application of a fluoride solution of 5,000 parts per million. Additional studies in this field are essential to determine the effectiveness of this therapy, the most desirable fluoride solution, the most efficacious concentration and the optimal number of applications to the teeth.

No practical hazards are known at this time, but much research is still needed to clarify some of the points discussed before recommendations for its general use seem warranted.

BURNS FROM LITHIUM

To the Editor:—An industrial plant has asked me to outline treatment and prophylaxis for burns by lithium chloride and hydroxide which occur on the hands, arms, face and legs and are penetrating, ulcerating burns. Is there any preparation that can be applied to the exposed surfaces for prevention?

M.D., Pennsylvania.

ANSWER.—Lithium is a soft metal with a silvery luster, having a specific gravity of 0.59. It melts at 180°F. and burns at 200°F. In order to prevent it from oxidizing, it is kept in petroleum. It readily decomposes in water, forming lithium hydroxide. Lithium, therefore, closely resembles sodium. Lithium chloride is similar to sodium chloride except that it deliquesces in air. Lithium hydroxide is caustic in its action, similar to sodium hydroxide. If lithium chloride enters abrasions it can cause erosion and ulceration of the skin. Lithium hydroxide can cause ulcers in the skin and in the nasal mucosa similar to those caused by sodium hydroxide.

The prevention of burns by lithium hydroxide is the same as the prevention of burns from sodium hydroxide; namely, those handling the material should wear rubber gauntlets and rubber aprons in order to protect the arms and legs. Transparent face shields will give protection to the face. Protective ointments are less efficacious. If they are used they should be of the lanolin-castor oil type described as type 3 in "Protective Ointments and Industrial Cleansers" by Louis Schwartz, published in the *Medical Clinics of North America* (26:1195 [July] 1942). The workers should also be instructed to insert petroleum jelly in the nostrils several times a day. In addition to this the tanks, vats or other containers of lithium hydroxide should be covered when not in use and vented by suction vents when they are in use so as to prevent exposure from vapors.

Workers should be instructed that if they get lithium hydroxide on the skin or clothing they should immediately flush it with water. Ulcers should be cleaned of crust and pus and treated aseptically.

SEDIMENT IN GASOLINE FUEL LINE

To the Editor:—In trying to suck gasoline through the fuel pump on his automobile, a man received some finely granular precipitate in his mouth. About ten minutes later he complained of severe burning of his mouth and lips, as if he had been burned by a corrosive poison. However, there was slight, if any, coloration of the tissues. At the time he received this material in his mouth he vomited and later ate a good supper but during the night had severe cramps in the abdomen, which cleared up rapidly with a milk and egg diet and colcium gluconate intravenously. What is this sludge that forms in gasoline cans and carburetors? Does it contain lead? If so, how soluble is it and what amount would be necessary to cause an acute lead colic? How is tetraethyl lead poisonous? Is it other than as a lead poison or does the tetraethyl have any poisonous property and would this cause any other symptoms than an acute lead colic?

John G. Beck, M.D., Sturgeon Bay, Wis.

ANSWER.—Most of the sludge deposited along an automobile fuel line is ordinary dirt. This is admixed with traces of waxes, paraffins, zinc chloride and possibly a trace of lead and dyes. The quantity of any one substance is not likely to represent any prospective toxicity. If an appreciable quantity of gasoline was swallowed, this becomes the likely source of irritation of the mouth and lips, abdominal cramps, and similar symptoms. The quantity of tetraethyl lead in a gallon of gasoline does not lend plausibility to the idea of lead poisoning from an uncertain swallow of this material. Tetraethyl lead to a substantial degree resembles in its injurious properties other forms of lead but with two noteworthy differences: Tetraethyl lead along with some other organic compounds is absorbable through the skin, while inorganic lead compounds are not. Also tetraethyl lead appears to have a predilection for action on the central nervous system to an extent or frequency unknown for inorganic lead compounds. It may be doubted that in the instance described in this query any lead poisoning occurred.

HYPERTENSION AND OBSTRUCTION OF THE URINARY TRACT

To the Editor:—How is the hypertensive state associated with chronic urinary retention produced? Particularly in question is that type of hypertension which accompanies obstruction of the neck of the bladder which subsides after decompression.

M.D., North Carolina.

ANSWER.—Elevation of blood pressure following obstruction of the urinary tract has been frequently observed since its first description in the latter half of the nineteenth century. Secondary hypertension occurs in about one third of all cases of prostatic obstruction. The definite lowering of blood pressure after the relief of an obstruction in the urogenital tract has led many to postulate that all patients with hypertension have some interference with urinary flow. Many studies indicate that all urinary causes of hypertension must be excluded before the diagnosis of essential hypertension can be established. Since not all patients have a lowering of blood pressure on the relief of urinary obstruction, there are other causes of hypertension.

BIOPSY AND SPREAD OF CANCER TISSUE

To the Editor:—Can you give me statistics about the spreading of cancer cells after biopsy? Are there any clinical reports on that subject, especially concerning biopsy of cancerous diseases of the tonsils, tongue and larynx?

Zdenka V. De Dworak, M.D., Santa Monica, Calif.

ANSWER.—There is no evidence to indicate that biopsies performed under proper circumstances cause the spread of cancer cells. The literature contains numerous reports on the subject. There are probably no monographs dealing exclusively with this problem, but a discussion of the subject can be found in various textbooks dealing with cancer.

CONSTIPATION AND HYPERTROPHIED HUSTON'S VALVES

To the Editor:—A woman aged 60 has chronic constipation with an occasional tendency to slight prolapse. She has a mild cancer phobia. She was recently examined and told that the condition was probably due to hypertrophied Huston's valves, and an operation was advised to section the valves. She was told there would be seven to eight stools a day for several months and that she should remain in the vicinity for observation during this period. Is this a well recognized operation?

M.D., Colorado.

ANSWER.—Constipation due to hypertrophied Huston's valves is a rare contingency. Operations on these valves at no time remove the cause of the constipation. The inspissated stool is initiated higher up in the colon and has nothing at all to do with the valvular derangement of the rectum. Unless x-ray evidence can show that there is a definitely dilated colon above these valves, their enlargement plays no part in the disturbed physiology of the gastrointestinal tract. Frequently patients of this age group suffer from constipation due to vitamin B₁ deficiency. Furthermore, it has been noted that in these individuals hypothyroid manifestations are not at all uncommon. This phase of the clinical picture should be investigated thoroughly.

TICK REPELLENTS

To the Editor:—Can you tell me of any substance or combination of substances that will act as a repellent of ticks? The Ozarks abound with several varieties of them, the so-called seed ticks, deer ticks and others of like size. I am aware of methods of removal such as chloroform, kerosene and heat. Is there any repellent that will keep the ticks off the skin even if they do get on the clothing?

Wallace A. Belsey, M.D., Campbell, Mo.

ANSWER.—Indalone, sold by the Skol Company, Inc., 250 East 43d Street, New York City 17, has been well recommended as a repellent for ticks. This synthetic compound is alpha, alpha-dimethyl-alpha-carbo-butoxydihydro-gamma-pyrone.

Another material has been developed for use by the armed forces and is known as 622. Unfortunately, only enough supplies are available for the armed forces at the present time. Undoubtedly, when the needs of the armed forces have been satisfied, other tick repellents of great efficiency will be made available to the general public.

THE POSTWAR CHALLENGE TO ORTHOPEDIC SURGERY

CHAIRMAN'S ADDRESS

GUY A. CALDWELL, M.D.
NEW ORLEANS

It may be said that the specialty of orthopedics had its origin in 1780, when Jean-André Venel established in Orbe, Switzerland, the first orthopedic institute for the correction of curvatures and torsions of the spine.¹ Little more than tenotomies and mechanical corrections of deformities were developed, however, prior to the works of William John Little, who established the Royal Orthopaedic Hospital in London in 1837, and Hugh Owen Thomas of Liverpool (1834-1891), whose name is perpetuated in his extension splints.² Thus the specialty became recognized in England and America only about a century ago. It was nearly fifty years later, however, that Robert Jones and his associates in England and Whitman, Davis, Bradford, Lovett and others in America truly emancipated the specialty into orthopedic surgery as we know it today. Of the advent of surgery in orthopedics, Whitman² wrote "It transformed an ill found and static specialty to an important and progressive branch of surgery."

The impetus given to orthopedics by operative surgery found expression in America in the establishment of the American Orthopaedic Association and, a little later, the Section on Orthopedic Surgery of the American Medical Association. There was, however, no comparable organization in Great Britain before World War I, and Robert Jones and his associates were virtually the only widely known orthopedic surgeons in England. As Betts³ stated, "At the outbreak of war in 1914 orthopedics as a special branch of surgery was comparatively unknown in Britain and Australia."

EFFECT OF WORLD WAR I ON ORTHOPEDIC SURGERY

Sir Robert Jones recognized in the large number of wounded and disabled soldiers a challenge to orthopedic surgery, which, with his exceptional skill and knowledge combined with a marvelous personality and

ability to organize, he met with such success that the specialty emerged much stronger than ever before. James A. Dickson,⁴ my illustrious predecessor as chairman of this section, stated in his address, two years ago:

Under serious opposition Robert Jones was entrusted with the establishment of the first military orthopedic service in any country, having 200 beds at Alder Hey in Liverpool. The results were so striking that within a short period 33,000 beds were equipped and staffed with English and American orthopedic surgeons. . . . According to Goldthwait, 65 per cent of the casualties in the last war were orthopedic cases, and by the time of the armistice 569 officers had served with the Orthopedic Division of the American Expeditionary Forces.

In a discussion of the evolution of orthopedic surgery Freiberg⁵ has aptly indicated the stimulus which World War I provided in the progress of orthopedics:

The World War had a great influence on orthopedic surgery, especially in Great Britain and in the United States. . . . By reason of the wider contacts which military experience brought to orthopedic surgeons, reciprocal relationships with their colleagues, of more intimate nature than civil life had furnished, were established. . . . They returned from military to civil life with their own professional concepts greatly expanded . . . very few of them resumed their civil occupations without profound alteration in their attitude toward their professional activities and toward their colleagues. . . . From the time when the identity of the orthopedic surgeon became recognized, the care and the rehabilitation of the cripple has been his particular province.

PROGRESS DURING PEACETIME

Because the medical officers assigned to orthopedic services during World War I returned to their civil occupations with "profound alteration in their attitude toward their professional activities and toward their colleagues,"⁵ rapid advancement of the specialty continued during peacetime. Numerous articles, journals and books began to appear in the literature. The American and British orthopedic associations flourished, the Section on Orthopedic Surgery of the American Medical Association became more active and soon many smaller groups appeared. Then, twelve years ago, the Academy of Orthopaedic Surgery was organized and two years later the American Board of Orthopaedic Surgery. The combined influence of these various groups and individuals began to be felt in medical schools, hospitals, communities, states and the entire nation. As a result a state and federal program was inaugurated to provide care for crippled children under the Social Security Act, the validity of the expert

opinions of orthopedists was recognized in courts and by compensation commissions on disability ratings, and the National Foundation for Infantile Paralysis and similar agencies were organized.

Although expansion of orthopedic surgery as a specialty was rapid during the twenty-four year interval of peace, it failed to keep pace of the demand. So well defined is the role of the orthopedic surgeon in the tables of organization of the armed forces that immediate demand for all physically fit surgeons under 45 years of age was made on the profession. The response was prompt, but unfortunately the number available was all too small. Whereas 288 surgeons certified by the American Board of Orthopaedic Surgery are now serving with the armed forces in responsible positions, each of them is being assisted by three or more partly trained orthopedic surgeons or general surgeons. In this way a large new group, approximately 900, is being drawn into intimate contact with the specialty and it is safe to predict that more than half of these will complete their training after the war, will limit their practice to this specialty and ultimately will be certified as orthopedic surgeons. Meanwhile a greatly diminished, nevertheless considerable, number of younger men, disqualified for military service, are continuing their training in routine channels at home. It is highly probable, therefore, that within the next five or ten years the number of men certified in the specialty of orthopedic surgery will be doubled or perhaps trebled, until it will reach 2,000 to 2,500 men in the United States.

At first glance it might appear that such rapid increase in the number of men certified to practice orthopedic surgery might overcrowd the specialty. If we study the probable postwar demands, however, it appears likely that the requirements will be far greater than the increased numbers can serve. The contacts of hundreds of thousands of young men and women now in the armed forces with organized orthopedic services are numerous. From the induction centers, where part of the physical examination is done by orthopedists, to minor or major injuries received while in training and treated on orthopedic services of the camp or station hospitals, on through combat duty, when those with wounds in the extremity trail back through evacuation hospitals to the orthopedic services of the general hospitals abroad and at home, thousands on thousands will learn for the first time the value of special training and skill in the care of crippling diseases and injuries. This knowledge is shared by other thousands of their buddies, families and hospital attendants and will go back with them into civil life. From the homes and families established by these men it is certain that greater and more frequent demands will be made for orthopedic care.

Large numbers of professional personnel with the armed forces—physicians and nurses not assigned to orthopedic services—are daily brought face to face with the fact that in army hospitals throughout this country 35 to 40 per cent of the patients are in orthopedic services, and in the combat areas 65 per cent of the wounded have injuries of the extremities. They perforce become "orthopedic conscious" by daily reference of patients and requests for orthopedic consultations. On their return to civil life it will be second nature to refer such patients for orthopedic care.

During the early postwar period Veterans' Facilities must necessarily be greatly expanded and the orthopedic services conspicuously enlarged. Already the Vocational Training and Rehabilitation Program under the Social Security Act as amended in June 1943 is providing a system for medical care which will include a large percentage of orthopedic cases. State crippled children's services, which have been compelled to operate with skeleton staffs, will enlarge to their former size, and many new organizations will lend aid to orthopedic programs.

Therefore the postwar demand on the specialty of orthopedic surgery will be strikingly increased as a result of our awakened consciousness of the meaning and value of orthopedic service through observation of its work in the armed forces by thousands of lay and professional workers who will eventually return to civil life in widely scattered areas. Their demands will be supplemented by those growing out of the gradual spread and natural growth of civilian orthopedics through development and expansion of the programs for crippled children and vocational rehabilitation. Soon the man in the street will cease to stammer and stall when he attempts to pronounce orthopedist and to confuse the term with osteopath, chiropractor and chiropodist. Moreover, the public is rapidly realizing the truth of Freiberg's statement that "from the time when the identity of the orthopedic surgeon became recognized the care and the rehabilitation of the cripple has been his particular province."

The postwar challenge to orthopedic surgery is presented by the assurance of an overwhelming demand for its assistance to rehabilitate the cripples and the equal certainty that, although the number of trained orthopedists available to meet this demand will be greatly increased, it will be insufficient. In 1942 there were 180,496 physicians in the United States, only 707 of whom were certified orthopedists, or 0.39 per cent. When this small percentage is balanced against the fact that in military hospitals about 40 per cent of the work is assigned to orthopedic services, it is not improbable that postwar civilian demands will require that 20 to 25 per cent of its hospital population be cared for by orthopedists. If we assume that the number of physicians will be 200,000 and the increased number of orthopedic surgeons 2,000, we are confronted by a situation in which 1 per cent of the physicians will be trying to care for 20 to 25 per cent of the hospitalized patients.

What can we do to meet this challenge? First, we must inventory our assets and organize them to meet this situation to the best advantage. It is obvious that the basic need is for the rapid but efficient training of a large number of younger physicians. To accomplish this it will be necessary for every practicing orthopedist to constitute himself a teacher and use his facilities and time to assist in training several younger men to succeed him. More articles, periodicals and books on orthopedic problems should be published. Organizations such as this one, the orthopedic section of the greatest medical association in the world, together with the American Orthopedic Association, the Academy and all of the smaller, more intimate, groups should plan constructive programs of instruction that will awaken interest and attract younger men to the field of orthopedic surgery. Medical schools and their

graduate departments should enlarge their facilities and apportion their time to provide more emphasis on instruction in this surgical specialty. Hospitals should begin to organize their orthopedic services for approved resident training in this special branch of surgery. Nursing schools should encourage some of their graduates to specialize in this field and others to train in physical therapy and occupational therapy.

At present the report of the Council on Medical Education and Hospitals lists only 84 approved resident training services in orthopedic surgery, most of these in the older centers or affiliated with universities or hospitals for crippled children. A survey of hospitals having orthopedic services for crippled children staffed by specialists certified by the American Board of Orthopaedic Surgery reveals 200 services which should be qualified and approved for training. Many other general hospitals have large services for fractures and other traumatic injuries of the extremities that have sufficient clinical material under competent supervision to provide adequate training for orthopedic residents for at least one of the three required years. Every medical school in the country can and should provide six months of graduate training, especially in the basic sciences of anatomy, pathology, physiology and biochemistry, to supplement the training of men who may acquire their clinical experience in hospitals and clinics not affiliated with universities.

Retired or demobilized medical officers will be eligible for graduate training in various specialties with governmental pay. Advantage should be taken of this to offer supplementary training to all officers who have served in orthopedic services with the armed forces and to attract additional young men who have been serving with the field units. Experienced orthopedic surgeons now in the service who are capable of teaching should be demobilized and returned to their teaching posts as rapidly as possible to assist in this great move. Every one of us must look ahead and begin now to arrange his work and hospital service to provide time and facilities for instruction for those who will be needed to meet this great postwar need.

SUMMARY

As rapid as have been the advances of the specialty of orthopedic surgery during the last fifty years, it has been unable to keep abreast of the increasing demand. World War II has accentuated the demand without helping materially to increase the number of trained orthopedists to meet it. It appears probable that in the postwar period 1 per cent of the physicians specializing in orthopedic surgery will be required to care for 20 to 25 per cent of the hospitalized civilians. It is therefore urgent that more men be trained in the specialty. To provide orthopedic training for the number of physicians who will be needed in the postwar era, all available hospital services should be qualified for approval by the Council on Medical Education and Hospitals and the American Board of Orthopaedic Surgery, and all medical schools should expand their teaching facilities for orthopedics, especially their graduate courses in the basic sciences of anatomy, pathology, physiology and biochemistry.

A PSYCHIATRIC STUDY OF SUCCESSFUL SOLDIERS

CAPTAIN JACK G. SHEPS

ROYAL CANADIAN ARMY MEDICAL CORPS

Studies of soldiers who broke down in training or under what was considered to be minimal stress in battle led to the establishment of present standards for psychiatric screening. These standards have been criticized on the grounds that they were based on observations of selected groups. It has been suggested that men with good motivation and a desire to serve can cover up and compensate for psychoneurosis. This paper is an attempt to test our psychiatric screening standards by a study of 116 successful soldiers and compares the findings with those obtained in studies of neurotic soldiers.

Studies of neurotic soldiers have been done by Rosenberg¹ and Slater.² Ebaugh³ and his associates studied 100 soldiers designated as well adjusted by their officers and compared them with 100 psychiatric cases. Uninjured combat veterans with no complaints were studied by Schwab, Finesinger and Brazier⁴ and compared with cases of combat neurosis and neurosis developed in training. Steinberg and Wittman⁵ studied ordinary soldiers and compared them with a group of neurotic and psychotic patients.

This is a study of 115 soldiers and 1 sailor. Fifty-eight at several camps in various phases of training were chosen by their training officers as the best all around men in a group—usually a platoon. Fifty-seven soldiers and 1 sailor injured in a theater of action were also studied. These men entered the service before psychiatric screening was established, but they were all front line fighting troops and had no presenting psychiatric disabilities. Men from base areas or lines of communication, subject only to air raids, were excluded. In the case of the soldiers in training, a short report from the training officer accompanied the man explaining why he was chosen, together with a note by the personnel selection officer. A limited social service investigation was done in every case. A psychiatric interview of at least thirty minutes was carried out. The purpose of the study was outlined and the man's cooperation enlisted. It was stressed that the interview was unofficial and would in no way affect the soldier's career in the Army or the matter of pensions. All the men cooperated very well and spoke freely. Most of the combat veterans came from two regiments, and it was possible to check on their behavior with others in the same unit. Two of the veterans

enjoyed a more intimate relationship—they were wounded by the same bomb. The study was restricted to noncommissioned men; all but 9 were privates. The soldiers in training had been in the Army from three to eight months and the combat veterans from two to four years, about half having been wounded in the Sicilian campaign and half in the Italian campaign. After each interview the man was graded as if he were a candidate for enlistment, without taking into consideration his progress and record in the Army.

FINDINGS
